(54) Title: REGULATED TRANSCRIPTION OF TARGETED GENES AND OTHER BIOLOGICAL EVENTS

(57) Abstract

Dimerization and oligomerization of proteins are general biological control mechanisms that contribute to the activation of numerous cellular processes. We have developed a general procedure for the regulated (inducible) dimerization or oligomerization of intracellular proteins. As outlined in the figure, any two target proteins can be induced to associate by treating the cells or organisms that harbor them with cell permeable, synthetic ligands. In summary, we have induced: (1) the intracellular aggregation of the cytoplasmic tail of the zeta chain of the T cell receptor (TCR)-CD3 complex thereby leading to signaling and transcription of a reporter gene, (2) the homodimerization of the cytoplasmic tail of the Fas receptor thereby leading to cell-specific apoptosis (programmed cell death) and (3) the heterodimerization of a DNA-binding domain (Gal4) and a transcription-activation domain (VP16) thereby leading to direct transcription of a reporter gene.

Regulated Transcription Of Targeted Genes and Other Biological Events

Technical Field

5 This invention concerns materials, methods and applications relating to the oligomerizing of chimeric proteins with a dimeric or multimeric, preferably non-peptidic, organic molecule. Aspects of the invention are exemplified by recombinant modifications of host cells and their use in gene therapy or other applications of inducible gene expression.

10

Introduction

Biological specificity usually results from highly specific interactions among proteins. This principle is exemplified by signal transduction, the process by which extracellular molecules influence intracellular events. Many pathways originate with the binding of extracellular ligands to cell surface
15 receptors. In many cases receptor dimerization leads to transphosphorylation and the recruitment of proteins that continue the signaling cascade. The realization that membrane receptors could be activated by homodimerization resulted from the observation that receptors could be activated by antibodies that cross linked two receptors. Subsequently, many receptors were found to
20 share those properties. The extracellular and transmembrane regions of many receptors are believed to function by bringing the cytoplasmic domains of the receptors in close proximity by a ligand-dependent dimerization or oligomerization, while the cytoplasmic domains of the receptor convey specific
25 signals to internal compartments of the cell.

Others have investigated ligand-receptor interactions in different systems. For example, Clark, et al., Science (1992) 258, 123 describe cytoplasmic effectors of the B-cell antigen receptor complex. Durand, et al., Mol. Cell. Biol. (1988) 8, 1715, Verweij, et al., J. Biol. Chem. (1990) 265, 15788
30 and Shaw, et al., Science (1988) 241, 202 report that the NF-AT-directed transcription is rigorously under the control of the antigen receptor. Inhibition of NF-AT-directed transcription by cyclosporin A and FK506 is reported by Emmel, et al., Science (1989) 246, 1617 and Flanagan, et al., Nature (1991) 352, 803. Durand, et al., Mol. Cell. Biol. (1988) 8, 1715 and Mattila, et al., EMBO J.
35 (1990) 9, 4425 describe the NF-AT binding sites. References describing the ζ chain include Orloff, et al., Nature (1990) 347, 189-191; Kinet, et al., Cell (1989) 57, 351-354; Weissman, et al., Proc. Natl. Acad. Sci. USA (1988) 85,

9709-9713 and Lanier, *Nature* (1989) 342, 803-805. A CD4 immunoadhesin is described by Byrn, et al. *Nature* (1990) 344, 667-670. A CD8- ζ -fused protein is described by Irving, et al., *Cell* (1992) 64, 891. See also, Letourner and Klausner, *Science* (1992) 255, 79.

20 However, as will be clear from this disclosure, none of the foregoing authors describe or suggest the present invention. Our invention, which is disclosed in detail hereinafter, involves a generally applicable method and materials for utilizing protein homodimerization, heterodimerization and oligomerization in living cells. Chimeric responder proteins are intracellularly
25 expressed as fusion proteins with a specific receptor domain. Treatment of the cells with a cell permeable multivalent ligand reagent which binds to the receptor domain leads to dimerization or oligomerization of the chimera. In analogy to other chimeric receptors (see e.g. Weiss, *Cell* (1993) 73, 209), the chimeric proteins are designed such that oligomerization triggers the desired subsequent
30 events, e.g. the propagation of an intracellular signal via subsequent protein-protein interactions and thereby the activation of a specific subset of transcription factors. The initiation of transcription can be detected using a reporter gene assay. Intracellular crosslinking of chimeric proteins by synthetic ligands has potential in basic investigation of a variety of cellular processes and
35 in regulating the synthesis of proteins of therapeutic or agricultural importance. Furthermore, ligand mediated oligomerization now permits regulated gene therapy. In so doing, it provides a fresh approach to increasing the safety,

expression level and overall efficacy obtained with gene therapy.

Summary Of The Invention

This invention provides novel chimeric (or "fused") proteins and small
5 organic molecules capable of oligomerizing the chimeric proteins. The chimeric
proteins contain at least one ligand-binding (or "receptor") domain fused to an
additional ("action") domain, as described in detail below. As will also be
described, the chimeric proteins may contain additional domains as well. These
chimeric proteins are recombinant in the sense that the various domains are
10 derived from different sources, and as such, are not found together in nature
(i.e., are heterologous).

Genes, i.e., RNA or preferably DNA molecules referred to herein as
"genetic" or "DNA" constructs) which encode the novel chimeric proteins, and
optionally target genes, are provided for the genetic engineering of host cells.
15 Also provided are methods and compositions for producing and using such
modified cells. The engineered cells of this invention contain at least one such
chimeric protein or a first series of genetic constructs encoding the chimeric
protein(s). These constructs are recombinant in the sense that the component
portions, e.g. encoding a particular domain or expression control sequence, are
20 not found directly linked to one another in nature (i.e., are heterologous).

One DNA construct of this invention encodes a chimeric protein
comprising (a) at least one receptor domain (capable of binding to a selected
ligand) fused to (b) a heterologous additional ("action") protein domain.
Significantly, the ligand is capable of binding to two (or more) receptor domains,
25 i.e. to chimeric proteins containing such receptor domains, in either order or
simultaneously, preferably with a K_d value below about 10^{-6} , more preferably
below about 10^{-7} , even more preferably below about 10^{-8} , and in some
embodiments below about 10^{-9} M. The ligand preferably is a non-protein and
has a molecular weight of less than about 5 kDa. The receptor domains of the
30 chimeric proteins so oligomerized may be the same or different. The chimeric
proteins are capable of initiating a biological process upon exposure to the
ligand, i.e., upon oligomerization with each other. The encoded chimeric protein
may further comprises an intracellular targeting domain capable of directing the
chimeric protein to a desired cellular compartment. The targeting domain can be
35 a secretory leader sequence, a membrane spanning domain, a membrane binding
domain or a sequence directing the protein to associate with vesicles or with the
nucleus, for instance.

The action domains of the chimeric proteins may be selected from a broad variety of protein domains capable of effecting a desired biological result upon oligomerization of the chimeric protein(s). For instance, the action domain may comprise a protein domain such as a CD3 zeta subunit capable, upon
5 exposure to the ligand and subsequent oligomerization, of initiating a detectable intracellular signal; a DNA-binding protein such as Gal 4; or a transcriptional activation domain such as VP16. Numerous other examples are provided herein. One example of a detectable intracellular signal is a signal activating the transcription of a gene under the transcriptional control of a transcriptional
10 control element (e.g. enhancer/promoter elements and the like) which is responsive to the oligomerization.

As is discussed in greater detail later, in various embodiments of this invention the chimeric protein is capable of binding to an FK506-type ligand, a cyclosporin A-type ligand, tetracycline or a steroid ligand. Such binding leads to
15 oligomerization of the chimeric protein with other chimeric protein molecules which may be the same or different.

Optionally the cells further contain a second recombinant genetic construct, or second series of such construct(s), containing a target gene under the transcriptional control of a transcriptional control element (e.g.
20 promoter/enhancer) responsive to a signal triggered by ligand-mediated oligomerization of the chimeric proteins, i.e. to exposure to the ligand. These constructs are recombinant in the sense that the target gene is not naturally under the transcriptional control of the responsive transcriptional control element.

25 In one aspect of the invention the DNA construct contains (a) a transcriptional control element responsive to the oligomerization of a chimeric protein as described above, and (b) flanking DNA sequence from a target gene permitting the homologous recombination of the transcriptional control element into a host cell in association with the target gene. In other embodiments the construct contains a desired gene and flanking DNA sequence from a target
30 locus permitting the homologous recombination of the target gene into the desired locus. The construct may also contain the responsive transcriptional control element, or the responsive element may be provided by the locus. The target gene may encode a surface membrane protein, a secreted protein, a
35 cytoplasmic protein or a ribozyme or an antisense sequence.

The constructs of this invention may also contain a selectable marker permitting transfection of the constructs into host cells and selection of

transfectants containing the construct. This invention further encompasses DNA vectors containing such constructs, whether for episomal transfection or for integration into the host cell chromosomes. The vector may be a viral vector, including for example an adeno-, adeno associated- or retroviral vector.

5 This invention further encompasses a chimeric protein encoded by any of our DNA constructs, as well as cells containing and/or expressing them, including procaryotic and eucaryotic cells and in particular, yeast, worm, insect, mouse or other rodent, and other mammalian cells, including human cells, of various types and lineages, whether frozen or in active growth, whether in
10 culture or in a whole organism containing them.

For example, in one aspect, this invention provides cells, preferably but not necessarily mammalian, which contain a first DNA construct encoding a chimeric protein comprising (i) at least one receptor domain capable of binding
15 to a selected oligomerizing ligand of this invention and (ii) another protein domain, heterologous with respect to the receptor domain, but capable, upon oligomerization with one or more other like domains, of triggering the activation of transcription of a target gene under the transcriptional control of a
transcriptional control element responsive to said oligomerization. The cells
20 further contain a target gene under the expression control of a transcriptional control element responsive to said oligomerization ligand. Following exposure to the selected ligand expresses the target gene.

In another aspect, the invention provides cells which contain a first set of DNA constructs encoding a first chimeric protein containing a DNA-binding domain and at least one receptor domain capable of binding to a first selected
25 ligand moiety. The cell further a second chimeric protein containing a transcriptional activating domain and at least one receptor domain capable of binding to a second selected ligand (which may be the same or different from the first selected ligand moiety). The cell additional contains a DNA construct encoding a target gene under the transcriptional control of a heterologous
30 transcriptional control sequence which binds with the DNA-binding domain and is responsive to the transcriptional activating domain such that the cell expresses the target gene following exposure to a substance containing the selected ligand moiety(ies).

Also provided are A DNA composition comprising a first DNA
35 construct encoding a chimeric protein comprising at least one receptor domain, capable of binding to a selected ligand, fused to a heterologous additional protein domain capable of initiating a biological process upon exposure to the

oligomerizing ligand, i.e. upon oligomerization of the chimeric protein; and a second DNA construct encoding a target gene under the transcriptional control of a transcription control element responsive to the oligomerization ligand.

Another exemplary DNA composition of this invention comprises a first series of DNA constructs encoding a first and second chimeric protein and a second DNA construct encoding a target gene under the transcriptional control of an transcription control element responsive to the oligomerization of the chimeric protein molecules. The DNA construct encoding the first chimeric protein comprises (a) at least one first receptor domain, capable of binding to a selected first ligand moiety, fused to (b) a heterologous additional protein domain capable of initiating a biological process upon [exposure to the oligomerization ligand, i.e. upon oligomerization of the first chimeric protein to a second chimeric protein molecule. The DNA construct encoding the second chimeric protein comprises (i) at least one receptor domain, capable of binding to a selected second ligand moiety, fused to (ii) a heterologous additional protein domain capable of initiating a biological process upon exposure to the oligomerization ligand, i.e., upon oligomerization to the first chimeric protein. The first and second receptor moieties in such cases may be the same or different and the first and second selected ligand moieties may likewise be the same or different.

Our ligands are molecules capable of binding to two or more chimeric protein molecules of this invention to form an oligomer thereof, and have the formula:

linker—{rbm₁, rbm₂, ...rbm_n}

wherein n is an integer from 2 to about 5, rbm(1)-rbm(n) are receptor binding moieties which may be the same or different and which are capable of binding to the chimeric protein(s). The rbm moieties are covalently attached to a linker moiety which is a bi- or multi-functional molecule capable of being covalently linked ("—") to two or more rbm moieties. Preferably the ligand has a molecular weight of less than about 5 kDa and is not a protein. Examples of such ligands include those in which the rbm moieties are the same or different and comprise an FK506-type moiety, a cyclosporin-type moiety, a steroid or tetracycline. Cyclosporin-type moieties include cyclosporin and derivatives thereof which are capable of binding to a cyclophilin, naturally occurring or modified, preferably with a K_d value below about 10⁻⁶ M. In some embodiments it is preferred that

the ligand bind to a naturally occurring receptor with a K_d value greater than about 10^{-6} M and more preferably greater than about 10^{-5} M. Illustrative ligands of this invention are those in which at least one rbm comprises a molecule of FK506, FK520, rapamycin or a derivative thereof modified at C9, C10 or both, which ligands bind to a modified receptor or chimeric molecule containing a modified receptor domain with a K_d value at least one, and preferably 2, and more preferably 3 and even more preferably 4 or 5 or more orders of magnitude less than their K_d values with respect to a naturally occurring receptor protein. Linker moieties are also described in detail later, but for the sake of illustration, include such moieties as a C2-C20 alkylene, C4-C18 azalkylene, C6-C24 N-alkylene azalkylene, C6-C18 arylene, C8-C24 aralkylene or C8-C36 bis-carboxamido alkylene moiety.

The monomeric rbm's of this invention, as well as compounds containing sole copies of an rbm, which are capable of binding to our chimeric proteins but not effecting dimerization or higher order oligomerization thereof (in view of the monomeric nature of the individual rbm) are oligomerization antagonists.

In one embodiment, genetically engineered cells of this invention can be used for regulated production of a desired protein. In that embodiment the cells, engineered in accordance with this invention to express a desired gene under ligand-induced regulation, are grown in culture by conventional means. Addition of the ligand to the culture medium leads to expression of the desired gene and production of the desired protein. Expression of the gene and production of the protein can then be turned off by adding to the medium an oligomerization antagonist reagent, as is described in detail below. Alternatively, this invention can be used to engineer ligand-inducible cell death characteristics into cells. Such engineered cells can then be eliminated from a cell culture after they have served their intended purpose (e.g. production of a desired protein or other product) by adding the ligand to the medium. Engineered cells of this invention can also be used in vivo, to modify whole organisms, preferably animals, including humans, e.g. such that the cells produce a desired protein or other result within the animal containing such cells. Such uses include gene therapy. Alternatively, the chimeric proteins and oligomerizing molecules can be used extracellularly to bring together proteins which act in concert to initiate a physiological action.

This invention thus provides materials and methods for achieving a biological effect in cells in response to the addition of an oligomerizing ligand. The method involves providing cells engineered in accordance with this

invention and exposing the cells to the ligand.

For example, one embodiment of the invention is a method for activating transcription of a target gene in cells. The method involves providing cells containing and capable of expressing (a) at least one DNA construct encoding a chimeric protein of this invention and (b) a target gene. The chimeric protein comprises at least one receptor domain capable of binding to a selected oligomerization ligand. The receptor domain is fused to an action domain capable—upon exposure to the oligomerizing ligand, i.e., upon oligomerization with one or more other chimeric proteins containing another copy of the action domain—of initiating an intracellular signal. That signal is capable of activating transcription of a gene, such as the target gene in this case, which is under the transcriptional control of a transcriptional control element responsive to that signal. The method thus involves exposing the cells to an oligomerization ligand capable of binding to the chimeric protein in an amount effective to result in expression of the target gene. In cases in which the cells are growing in culture, exposing them to the ligand is effected by adding the ligand to the culture medium. In cases in which the cells are present within a host organism, exposing them to the ligand is effected by administering the ligand to the host organism. For instance, in cases in which the host organism is an animal, in particular, a mammal (including a human), the ligand is administered to the host animal by oral, bucal, sublingual, transdermal, subcutaneous, intramuscular, intravenous, intra-joint or inhalation administration in an appropriate vehicle therefor.

This invention further encompasses a pharmaceutical composition comprising an oligomerization ligand of this invention in admixture with a pharmaceutically acceptable carrier and optionally with one or more pharmaceutically acceptable excipients for activating the transcription of a target gene, for example, or effecting another biological result of this invention, in a subject containing engineered cells of this invention. The oligomerization ligand can be a homo-oligomerization reagent or a hetero-oligomerization reagent as described in detail elsewhere. Likewise, this invention further encompasses a pharmaceutical composition comprising an oligomerization antagonist of this invention admixture with a pharmaceutically acceptable carrier and optionally with one or more pharmaceutically acceptable excipients for reducing, in whole or part, the level of oligomerization of chimeric proteins in engineered cells of this invention in a subject, and thus for de-activating the transcription of a target gene, for example, or turning off another biological result of this invention. Thus, the use of the oligomerization reagents and of the oligomerization

antagonist reagents to prepare pharmaceutical compositions is encompassed by this invention.

This invention also offers a method for providing a host organism, preferably an animal, and in many cases a mammal, responsive to an oligomerization ligand of this invention. The method involves introducing into
5 the organism cells which have been engineered in accordance with this invention, i.e. containing a DNA construct encoding a chimeric protein hereof, and so forth. Alternatively, one can introduce the DNA constructs of this invention into a host organism, e.g. mammal under conditions permitting transfection of one or
10 more cells of the host mammal.

We further provide kits for producing cells responsive to a ligand of this invention. One kit contains at least one DNA construct encoding one of our chimeric proteins containing at least one receptor domain and an action domain (as they are described elsewhere). The kit may contain a quantity of a ligand of
15 this invention capable of oligomerizing the chimeric protein molecules encoded by the DNA constructs of the kit, and may contain in addition a quantity of an oligomerization antagonist, e.g. monomeric ligand reagent. Where a sole chimeric protein is encoded by the construct(s), the oligomerization ligand is a homo-oligomerization ligand. Where more than one such chimeric protein is encoded, a
20 hetero-oligomerization ligand may be included. The kit may further contain a "second series" DNA construct encoding a target gene and/or transcription control element responsive to oligomerization of the chimeric protein molecules. The DNA constructs will preferably be associated with one or more selection markers for convenient selection of transfectants, as well as other conventional
25 vector elements useful for replication in prokaryotes, for expression in eukaryotes, and the like. The selection markers may be the same or different for each different DNA construct, permitting the selection of cells which contain each such DNA construct(s).

For example, one kit of this invention contains a first DNA construct
30 encoding a chimeric protein containing at least one receptor domain (capable of binding to a selected ligand), fused to a transcriptional activator domain; a second DNA construct encoding a second chimeric protein containing at least one receptor domain (capable of binding to a selected ligand), fused to a DNA binding domain; and a third DNA construct encoding a target gene under the
35 control of a transcriptional control element containing a DNA sequence to which the DNA binding domain binds and which is transcriptionally activated by exposure to the ligand in the presence of the first and second chimeric proteins.

Alternatively, a DNA construct for introducing a target gene under the control of a responsive transcriptional control element may contain a cloning site in place of a target gene to provide a kit for engineering cells to inducibly express a gene to be provided by the practitioner.

5 Other kits of this invention may contain one or two (or more) DNA constructs for chimeric proteins in which one or more contain a cloning site in place of an action domain (transcriptional initiation signal generator, transcriptional activator, DNA binding protein, etc.), permitting the user to insert whichever action domain s/he wishes. Such a kit may optionally include
10 other elements as described above, e.g. DNA construct for a target gene under responsive expression control, oligomerization ligand, antagonist, etc.

Any of the kits may also contain positive control cells which were stably transformed with constructs of this invention such that they express a reporter gene (for CAT, beta-galactosidase or any conveniently detectable gene product)
15 in response to exposure of the cells to the ligand. Reagents for detecting and/or quantifying the expression of the reporter gene may also be provided.

Brief Description Of The Figures

Fig. 1 is a diagram of the plasmid pSXNeo/IL2 (IL2-SX). In NF-AT-SX,
20 the *HindIII*-*Clal* DNA fragment from IL2-SX containing the IL2 enhancer/promoter, is replaced by a minimal IL-2 promoter conferring basal transcription and an inducible element containing three tandem NFAT-binding sites (described below).

25 Fig. 21A is an analysis of cyclophilin-Fas (and Fas-cyclophilin) fusion constructs in the transient transfection assay. MC3FE was shown to be the most effective in this series.

Fig. 21B depicts Immunophilin-Fas antigen chimeras and results of transient expression experiments in Jurkat T cells stably transformed with large T-antigen. Myr: the myristylation sequence taken from pp60^{c-src} encoding residues 1-14 (Wilson et al, *Mol & Cell Biol* 9 4 (1989): 1536-44); FKBP: human FKBP12; CypC: murine cyclophilin C sequence encoding residues 36-212 (Freidman et al, *Cell* 66 4 (1991): 799-806); Fas: intracellular domain of human Fas antigen encoding residues 179-319 (Oehm et al, *J Biol Chem* 267 15 (1992): 10709-15). Cells were electroporated with a plasmid encoding a secreted alkaline phosphatase reporter gene under the control of 3 tandem AP1

promoters along with a six fold molar excess of the immunophilin fusion construct. After 24 h the cells were stimulated with PMA (50ng/mL), which stimulates the synthesis of the reporter gene, and (CsA)2. At 48 h the cells were assayed for reporter gene activity. Western blots were performed at 24 h using
5 anti-HA epitope antibodies.

Fig. 22 depicts CAT assay results from Example 8.

Fig. 23 depicts the synthesis of modified FK-506 type compounds.

Description

10

I. Generic Discussion

This invention provides chimeric proteins, organic molecules for oligomerizing the chimeric proteins and a system for using them. The fused
15 proteins have a binding domain for binding to the (preferably small) organic oligomerizing molecules and an action domain, which can effectuate a physiological action or cellular process as a result of oligomerization of the chimeric proteins.

The basic concept for inducible protein association is illustrated in Figure
20 14. Ligands which can function as heterodimerization (or hetero-oligomerization, "HED") and homodimerization (or homo-oligomerization, "HOD") agents are depicted as dumbbell-shaped structures.

(Homodimerization and homo-oligomerization refer to the association of like components to form dimers or oligomers, linked as they are by the ligands of
25 this invention. Heterodimerization and hetero-oligomerization refer to the association of dissimilar components to form dimers or oligomers. Homo-oligomers thus comprise an association of multiple copies of a particular component while hetero-oligomers comprise an association of copies of different components. "Oligomerization", "oligomerize" and "oligomer", as the terms are
30 used herein, with or without prefixes, are intended to encompass "dimerization", "dimerize" and "dimer", absent an explicit indication to the contrary.)

Also depicted in Figure 14 are fusion protein molecules containing a target protein domain of interest ("action domain") and one or more receptor
35 domains that can bind to the ligands. For intracellular chimeric proteins, *i.e.*, proteins which are located within the cells in which they are produced, a cellular targeting sequence (including organelle targeting amino acid sequences)

will preferably also be present. Binding of the ligand to the receptor domains hetero- or homodimerizes the fusion proteins. Oligomerization brings the action domains into close proximity with one another thus triggering cellular processes normally associated with the respective action domain—such as TCR-mediated signal transduction, for example.

Cellular processes which can be triggered by oligomerization include a change in state, such as a physical state, *e.g.* conformational change, change in binding partner, cell death, initiation of transcription, channel opening, ion release, *e.g.* Ca^{+2} *etc.* or a chemical state, such as a chemical reaction, *e.g.* acylation, methylation, hydrolysis, phosphorylation or dephosphorylation, change in redox state, rearrangement, or the like. Thus, any such process which can be triggered by ligand-mediated oligomerization is included within the scope of this invention.

As a first application of the subject invention, cells are modified so as to be responsive to the oligomerizing molecules. The modified cells can be used in gene therapy, as well as in other applications where inducible transcription or translation (both are included under the term expression) is desired. The cells are characterized by a genome containing at least a first or first series (the series may include only one construct) of genetic constructs, and desirably a second or second series (the series may include only one construct) of constructs.

The nature and number of such genetic constructs will depend on the nature of the chimeric protein and the role it plays in the cell. For instance, in embodiments where the chimeric protein is to be associated with expression of a gene (and which may contain an intracellular targeting sequence or domain which directs the chimeric protein to be associated with the cellular surface membrane or with an organelle *e.g.* nucleus or vesicle), then there will normally be at least two series of constructs: a first series encoding the chimeric protein(s) which upon ligand-mediated oligomerization initiate a signal directing target gene expression, and desirably a second series which comprise the target gene and/or expression control elements therefor which are responsive to the signal.

Only a single construct in the first series will be required where a homooligomer, usually a homodimer, is involved, while two or more, usually not more than three constructs may be involved, where a heterooligomer is involved. The chimeric proteins encoded by the first series of constructs will be associated with actuation of gene transcription and will normally be directed to the surface membrane or the nucleus, where the oligomerized chimeric protein is able to

initiate, directly or indirectly, the transcription of one or more target genes. A second series of additional constructs will be required where an exogenous gene(s) is introduced, or where an exogenous or recombinant expression control sequence is introduced (e.g. by homologous recombination) for expression of an endogenous gene, in either case, whose transcription will be activated by the oligomerizing of the chimeric protein.

A different first series of constructs are employed where the chimeric proteins are intracellular and can act directly without initiation of transcription of another gene. For example, proteins associated with exocytosis can be expressed inducibly or constitutively, where the proteins will not normally complex except in the presence of the oligomerizing molecule. By employing proteins which have any or all of these properties which do not complex in the host cell; are inhibited by complexation with other proteins, which inhibition may be overcome by oligomerization with the ligand; require activation through a process which is not available in the host cell; or by modifying the proteins which direct fusion of a vesicle with the plasma membrane to form chimeric proteins, where the extent of complex formation and membrane fusion is enhanced in the presence of the oligomerizing molecule, exocytosis is or has the ability to be induced by the oligomerizing molecule.

Other intracellular proteins, such as kinases, phosphatases and cell cycle control proteins can be similarly modified and used.

Various classes of genetic constructs of this invention are described as follows:

(1) constructs which encode a chimeric protein comprising a binding domain and an action domain, where the binding domain is extracellular or intracellular and the action domain is intracellular such that ligand-mediated oligomerization of the chimeric protein, by itself (to form a homo-oligomer) or with a different fused protein comprising a different action domain (to form a hetero-oligomer), induces a signal which results in a series of events resulting in transcriptional activation of one or more genes;

(2) constructs which encode a chimeric protein having a binding domain and an action domain, where the binding domain and action domain are in the nucleus, such that ligand-mediated oligomerization of the protein, by itself (to form a homo-oligomer) or with a different fused protein comprising a different action domain (to form a hetero-oligomer), induces initiation of transcription directly via complexation of the oligomer(s) with the DNA transcriptional initiation region;

(3) constructs which encode a chimeric protein containing a binding domain and an action domain, where the binding domain and the action domain are cytoplasmic, such that ligand-mediated oligomerization of the protein, by itself (to form a homo-oligomer) or with a different fused protein comprising a different action domain (to form a hetero-oligomer), results in exocytosis; and

(4) constructs which encode a chimeric protein containing a binding domain and an action domain, where the binding domain and action domain are extracellular and the action domain is associated with initiating a biological activity (by way of non-limiting illustration, the action domain can itself bind to a substance, receptor or other membrane protein yielding, upon ligand-mediated oligomerization of the chimeras, the bridging of one or more similar or dissimilar molecules or cells); and,

(5) constructs which encode a destabilizing, inactivating or short-lived chimeric protein having a binding domain and an action domain, such that ligand-mediated oligomerization of the protein with a target protein comprising a different action domain leads to the destabilization and/or degradation or inactivation of said oligomerized target protein.

II. Transcription Regulation

The construct(s) of Groups (1) and (2), above, will be considered first. Group (1) constructs differ from group (2) constructs in their effect. Group (1) constructs are somewhat pleiotropic, i.e. capable of activating a number of wild-type genes, as well as the target gene(s). In addition, the response of the expression products of group (1) genes to the ligand is relatively slow. Group (2) constructs can be directed to a specific target gene and are capable of limiting the number of genes which will be transcribed. The response of expression products of group (2) constructs to the ligand is very rapid.

The subject system for groups (1) and (2) will include a first series of constructs which comprise DNA sequences encoding the chimeric proteins, usually involving from one to three, usually one to two, different constructs. The system usually will also include a second series of constructs which will provide for expression of one or more genes, usually an exogenous gene. By "exogenous gene" is meant a gene which is not otherwise normally expressed by the cell, e.g. because of the nature of the cell, because of a genetic defect of the cell, because the gene is from a different species or is a mutated or synthetic gene, or the like. Such gene can encode a protein, antisense molecule, ribozyme etc., or can be a DNA sequence comprising an expression control sequence linked or to be linked

to an endogenous gene with which the expression control sequence is not normally associated. Thus, as mentioned before, the construct can contain an exogenous or recombinant expression control sequence for ligand-induced expression of an endogenous gene.

5 The chimeric protein encoded by a construct of groups (1), (2) and (3) can have, as is often preferred, an intracellular targeting domain comprising a sequence which directs the chimeric protein to the desired compartment, *e.g.* surface membrane, nucleus, vesicular membrane, or other site, where a desired physiological activity can be initiated by the ligand-mediated oligomerization, at
10 least dimerization, of the chimeric protein.

 The chimeric protein contains a second ("binding" or "receptor") domain which is capable of binding to at least one ligand molecule. Since the ligand can contain more than one binding site or epitope, it can form dimers or higher order homo- or hetero-oligomers with the chimeric proteins of this invention. The
15 binding domain of the chimeric protein can have one or a plurality of binding sites, so that homooligomers can be formed with a divalent ligand. In this way the ligand can oligomerize the chimeric protein by having two or more epitopes to which the second domain can bind, thus providing for higher order oligomerization of the chimeric protein.

20 The chimeric protein also contains a third ("action") domain capable of initiating a biological activity upon ligand-mediated oligomerization of chimeric protein molecules via the binding domains. Thus, the action domain may be associated with transduction of a signal as a result of the ligand-mediated oligomerization. Such signal, for instance, could result in the initiation of
25 transcription of one or more genes, depending on the particular intermediate components involved in the signal transduction. See Figure 15 which depicts an illustrative chimeric protein in which the intracellular targeting domain comprises a myristate moiety; the receptor domain comprises three FKBP12 moieties; and the action domain comprises a zeta subunit. In other chimeric
30 proteins the action domains may comprise transcription factors, which upon oligomerization, result in the initiation of transcription of one or more target genes, endogenous and/or exogenous. The action domains can comprise proteins or portions thereof which are associated with fusion of vesicle membranes with the surface or other membrane, *e.g.* proteins of the SNAP and
35 SNARE groups (See, Sollner et al. (1993) 362, 318 and 353; Cell (1993) 72, 43).

A. Surface Membrane Receptor

Chimeric proteins of one aspect of this invention are involved with the surface membrane and are capable of transducing a signal leading to the transcription of one or more genes. The process involves a number of auxiliary
5 proteins in a series of interactions culminating in the binding of transcription factors to promoter regions associated with the target gene(s). In cases in which the transcription factors bind to promoter regions associated with other genes, transcription is initiated there as well. A construct encoding a chimeric protein of this embodiment can encode a signal sequence which can be subject to
10 processing and therefore may not be present in the mature chimeric protein. The chimeric protein will in any event comprise (a) a binding domain capable of binding a pre-determined ligand, (b) an optional (although in many embodiments, preferred) membrane binding domain which includes a transmembrane domain or an attached lipid for translocating the fused protein
15 to the cell surface/membrane and retaining the protein bound to the cell surface membrane, and, (c) as the action domain, a cytoplasmic signal initiation domain. The cytoplasmic signal initiation domain is capable of initiating a signal which results in transcription of a gene having a recognition sequence for the initiated signal in the transcriptional initiation region.

20 The gene whose expression is regulated by the signal from the chimeric protein is referred to herein as the "target" gene, whether it is an exogenous gene or an endogenous gene under the expression control of an endogenous or exogenous (or hybrid) expression control sequence. The molecular portion of the chimeric protein which provides for binding to a membrane is also referred
25 to as the "retention domain". Suitable retention domains include a moiety which binds directly to the lipid layer of the membrane, such as through lipid participation in the membrane or extending through the membrane, or the like. In such cases the protein becomes translocated to and bound to the membrane, particularly the cellular membrane, as depicted in Figure 15.

30

B. Nuclear Transcription Factors

Another first construct encodes a chimeric protein containing a cellular targeting sequence which provides for the protein to be translocated to the nucleus. This ("signal consensus") sequence has a plurality of basic amino
35 acids, referred to as a bipartite basic repeat (reviewed in Garcia-Bustos et al, Biochimica et Biophysica Acta (1991) 1071, 83-101). This sequence can appear in any portion of the molecule internal or proximal to the N- or C-terminus and

results in the chimeric protein being inside the nucleus. The practice of one embodiment of this invention will involve at least two ("first series") chimeric proteins: (1) one having an action domain which binds to the DNA of the transcription initiation region associated with a target gene and (2) a different
5 chimeric protein containing as an action domain, a transcriptional activation domain capable, in association with the DNA binding domain of the first chimeric protein, of initiating transcription of a target gene. The two action domains or transcription factors can be derived from the same or different protein molecules.

10 The transcription factors can be endogenous or exogenous to the cellular host. If the transcription factors are exogenous, but functional within the host and can cooperate with the endogenous RNA polymerase (rather than requiring an exogenous RNA polymerase, for which a gene could be introduced), then an exogenous promoter element functional with the fused transcription factors can
15 be provided with a second construct for regulating transcription of the target gene. By this means the initiation of transcription can be restricted to the gene(s) associated with the exogenous promoter region, i.e., the target gene(s).

A large number of transcription factors are known which require two subunits for activity. Alternatively, in cases where a single transcription factor
20 can be divided into two separate functional domains (e.g. a transcriptional activator domain and a DNA-binding domain), so that each domain is inactive by itself, but when brought together in close proximity, transcriptional activity is restored. Transcription factors which can be used include yeast GAL4, which can be divided into two domains as described by Fields and Song, *supra*. The
25 authors use a fusion of GAL4(1-147)-SNF1 and SNF4-GAL4(768-881), where the SNF1 and -4 may be replaced by the subject binding proteins as binding domains. Combinations of GAL4 and VP16 or HNF-1 can be employed. Other transcription factors are members of the Jun, Fos, and ATF/CREB families, Oct1, Sp1, HNF-3, the steroid receptor superfamily, and the like.

30 As an alternative to using the combination of a DNA binding domain and a naturally occurring activation domain or modified form thereof, the activation domain may be replaced by one of the binding proteins associated with bridging between a transcriptional activation domain and an RNA
polymerase, including but not limited to RNA polymerase II. These proteins
35 include the proteins referred to as TAF's, the TFII proteins, particularly B and D, or the like. Thus, one can use any one or combination of proteins, for example, fused proteins or binding motifs thereof, which serve in the bridge between the

DNA binding protein and RNA polymerase and provide for initiation of transcription. Preferably, the protein closest to the RNA polymerase will be employed in conjunction with the DNA binding domain to provide for initiation of transcription. If desired, the subject constructs can provide for three or more,
5 usually not more than about 4, proteins to be brought together to provide the transcription initiation complex.

Rather than have a transcriptional activation domain as an action domain, an inactivation domain, such as *ssn-6/TUP-1* or *Krüppel*-family suppressor domain, can be employed. In this manner, regulation results in
10 turning off the transcription of a gene which is constitutively expressed. For example, in the case of gene therapy one can provide for constitutive expression of a hormone, such as growth hormone, blood proteins, immunoglobulins, etc. By employing constructs encoding one chimeric protein containing a DNA binding domain joined to a ligand binding domain and another chimeric protein
15 containing an inactivation domain joined to a ligand binding domain, the expression of the gene can be inhibited via ligand-mediated oligomerization.

Constructs encoding a chimeric protein containing *inter alia* a ligand-binding domain fused to a transcriptional activating domain or subunit, transcriptional inactivating domain or DNA-binding domain are designed and
20 assembled in the same manner as described for the other constructs. Frequently, the N-terminus of the transcription factor will be bound to the C-terminus of the ligand-binding domain, although in some cases the reverse will be true, for example, where two individual domains of a single transcription factor are divided between two different chimeras.

25

III. Exocytosis

Another use for the ligand-mediated oligomerization mechanism is exocytosis, where export of a protein rather than transcription is controlled by the ligand. This can be used in conjunction with the expression of one or more
30 proteins of interest, as an alternative to providing for secretion of the protein(s) of interest via a secretory signal sequence. This embodiment involves two different first constructs. One construct encodes a chimeric protein which directs the protein to the vesicle to be integrated into the vesicular membrane as described by Sollner et al., *supra*. Proteins which may be used as the vesicle
35 binding protein include VAMP (synaptobrevin), *SNC2*, *rab3*, *SEC4*, synaptotagmin, *etc.*, individually or in combination. The cellular membrane protein may include syntaxin, *SSO1*, *SSO2*, *neurexin*, *etc.*, individually or in

combination. The other construct provides for transport to the surface membrane and employs the myristoyl signal sequence, other plasma membrane targeting sequence (*e.g.* for prenylation) or transmembrane retention domain, as described above. The encoded proteins are described in the above references and, all or functional part, may serve as the action domains. These constructs could be used in conjunction with the expression of an exogenous protein, properly encoded for transport to a vesicle or for an endocytotic endogenous protein, to enhance export of the endogenous protein.

Various mechanisms can be employed for exocytosis. Depending on the cell type and which protein is limiting for endocytosis in the cell, one or more of the vesicle bound proteins or cellular proteins may be encoded by one or more constructs having a response element which is activated by the ligand. Of particular interest is the combination of VAMP and syntaxin. Alternatively, one can provide for constitutive expression of non-limiting proteins controlling exocytosis, and provide for ligand regulated expression of the exocytosis limiting protein. Finally, one can provide for constitutive expression of the chimeric proteins associated with exocytosis, so that exocytosis is controlled by oligomerizing the chimeric proteins with the ligand. By employing appropriate binding domains, one can provide for different chimeric proteins to be oligomerized on the vesicle surface to form an active complex, and/or linking of the vesicle protein(s) with the cell membrane surface protein through the ligand. The chimeric proteins may not provide for exocytosis in the absence of the ligand due to modifications in the ligand which substantially reduce the binding affinity between the proteins governing exocytosis, such as deletions, mutations, *etc.* These modifications can be readily determined by employing overlapping fragments of the individual proteins and determining which fragments retain activity. The fragments can be further modified by using alanine substitutions to determine the individual amino acids which substantially affect binding. (Beohncke et al., J. Immunol. (1993) 150, 331-341; Evavold et al., *ibid* (1992) 148, 347-353).

The proteins assembled in the lumen of the vesicle, as well as the fused proteins associated with exocytosis can be expressed constitutively or inducibly, as described above. Depending on the purpose of the exocytosis, whether endogenous or exogenous proteins are involved, whether the proteins to be exported are expressed constitutively or inducibly, whether the same ligand can be used for initiating transcription of the fused proteins associated with exocytosis and the proteins to be exported, or whether the different proteins are

to be subject to different inducible signals, may determine the manner in which expression is controlled. In one aspect, the exocytosis mechanism would be the only event controlled by the ligand. In other aspects, both expression of at least one protein and exocytosis may be subject to ligand control.

5 Various proteins may be modified by introduction of a cellular targeting sequence for translocation of the protein to a vesicle without loss of the physiological activity of the protein. By using exocytosis as the delivery mechanism, relatively high dosages may be delivered within a short period of time to produce a high localized level of the protein or a high concentration in
10 the vascular system, depending on the nature of the host. Proteins of interest include e.g. insulin, tissue plasminogen activator, cytokines, erythropoietin, colony stimulating factors, growth factors, inflammatory peptides, cell migration factors.

 Coding sequences for directing proteins to a vesicle are available from
15 the vesicle binding proteins associated with exocytosis. See, for example, Sollner, et al. *supra*.

 Another use of the oligomerization mechanism is the control of protein degradation or inactivation. For example, a relatively stable or long-lived chimeric protein of this invention can be destabilized or targeted for degradation
20 by ligand-mediated oligomerization with a different chimeric protein of this invention which has a relatively short half-life or which otherwise destabilizes or targets the oligomer for degradation. In this embodiment, ligand-mediated oligomerization regulates biological functioning of a protein by conferring upon it in trans a shortened half-life. The latter chimeric protein may contain a domain
25 targeting the protein to the lysosome or a domain rendering the protein susceptible to proteolytic cleavage in the cytosol or nucleus or non-lysosomal organelle.

 The half-life of proteins within cells is determined by a number of factors which include the presence of short amino acid sequences within said protein
30 rich in the amino acid residues proline, glutamic acid, serine and threonine, hence "PEST", other sequences with similar function, protease sensitive cleavage sites and the state of ubiquitination. Ubiquitination is the modification of a protein by one or more units of the short polypeptide chain, ubiquitin, which targets proteins for degradation. The rate of ubiquitination of proteins is
35 considered to be determined primarily by the identity of the N-terminal amino acid of the processed protein and one or more unique lysine residues near the amino terminus.

IV. Other Regulatory Systems

Other biological functions which can be controlled by oligomerization of particular activities associated with individual proteins are protein kinase or
5 phosphatase activity, reductase activity, cyclooxygenase activity, protease activity or any other enzymatic reaction dependent on subunit association. Also, one may provide for association of G proteins with a receptor protein associated with the cell cycle, e.g. cyclins and cdc kinases, multiunit detoxifying enzymes.

V. Components of Constructs

The second or additional constructs (target genes) associated with group (1) and (2) chimeric proteins comprise a transcriptional initiation region having the indicated target recognition sequence or responsive element, so as to be
15 responsive to signal initiation from the activated receptor or activated transcription factors resulting in at least one gene of interest being transcribed to a sequence(s) of interest, usually mRNA, whose transcription and, as appropriate, translation may result in the expression of a protein and/or the regulation of other genes, e.g. antisense, expression of transcriptional factors, expression of membrane fusion proteins, etc.

For the different purposes and different sites, different binding domains and different cytoplasmic domains will be used. For chimeric protein receptors associated with the surface membrane, if the ligand-binding domain is extracellular, the chimeric protein can be designed to contain an extracellular
25 domain selected from a variety of surface membrane proteins. Similarly, different cytoplasmic or intracellular domains of the surface membrane proteins which are able to transduce a signal can be employed, depending on which endogenous genes are regulated by the cytoplasmic portion. Where the chimeric protein is internal, internal to the surface membrane protein or associated with an organelle, e.g. nucleus, vesicle, etc., the ligand-binding domain protein will be
30 restricted to domains which can bind molecules which can cross the surface membrane or other membrane, as appropriate. Therefore, these binding domains will generally bind to small naturally occurring or synthetic ligand molecules which do not involve proteins or nucleic acids.

A. Cytoplasmic domains

A chimeric protein receptor of Group (1) can contain a cytoplasmic domain from one of the various cell surface membrane receptors, including muteins thereof, where the recognition sequence involved in initiating transcription associated with the cytoplasmic domain is known or a gene responsive to such sequence is known. Mutant receptors of interest will dissociate transcriptional activation of a target gene from activation of genes which can be associated with harmful side effects, such as deregulated cell growth or inappropriate release of cytokines. The receptor-associated cytoplasmic domains of particular interest will have the following characteristics: receptor activation leads to initiation of transcription for relatively few (desirably fewer than 100) and generally innocuous genes in the cellular host; the other factors necessary for transcription initiated by receptor activation are present in the cellular host; genes which are activated other than the target genes will not affect the intended purpose for which these cells are to be used; oligomerization of the cytoplasmic domain or other available mechanism results in signal initiation; and joining of the cytoplasmic domain to a desired ligand-binding domain will not interfere with signalling. A number of different cytoplasmic domains are known. Many of these domains are tyrosine kinases or are complexed with tyrosine kinases, *e.g.* CD3 ζ , IL-2R, IL-3R, *etc.* For a review see Cantley, *et al.*, *Cell* (1991) 64, 281. Tyrosine kinase receptors which are activated by cross-linking, *e.g.* dimerization (based on nomenclature first proposed by Yarden and Ulrich, *Annu. Rev. Biochem.* (1988) 57, 443, include subclass I: EGF-R, ATR2/neu, HER2/neu, HER3/c-erbB-3, Xmrk; subclass II: insulin-R, IGF-1-R [insulin-like growth factor receptor], IRR; subclass III: PDGF-R-A, PDGF-R-B, CSF-1-R (M-CSF/c-Fms), c-kit, STK-1/Flk-2; and subclass IV: FGF-R, flg [acidic FGF], bek [basic FGF]); neurotrophic tyrosine kinases: Trk family, includes NGF-R, Ror1,2. Receptors which associate with tyrosine kinases upon cross-linking include the CD3 ζ -family: CD3 ζ and CD3 η (found primarily in T cells, associates with Fyn); β and γ chains of Fc ϵ RI (found primarily in mast cells and basophils); γ chain of Fc γ RIII/CD16 (found primarily in macrophages, neutrophils and natural killer cells); CD3 γ , δ , and ϵ (found primarily in T cells); Ig- α /MB-1 and Ig- β /B29 (found primarily in B cell). Many cytokine and growth factor receptors associate with common β subunits which interact with tyrosine kinases and/or other signalling molecules and which can be used as cytoplasmic domains in chimeric proteins of this invention. These include (1) the common β subunit

shared by the GM-CSF, IL-3 and IL-5 receptors; (2) the β chain gp130 associated with the IL-6, leukemia inhibitory factor (LIF), ciliary neurotrophic factor (CNTF), oncostatin M, and IL-11 receptors; (3) the IL-2 receptor γ subunit associated also with receptors for IL-4, IL-7 and IL-13 (and possibly IL-9); and (4) the β chain of the IL-2 receptor which is homologous to the cytoplasmic domain of the G-CSF receptor.

The interferon family of receptors which include interferons α/β and γ (which can activate one or more members of the JAK, Tyk family of tyrosine kinases) as well as the receptors for growth hormone, erythropoietin and prolactin (which also can activate JAK2) can also be used as sources for cytoplasmic domains.

Other sources of cytoplasmic domains include the TGF- β family of cell surface receptors (reviewed by Kingsley, D., *Genes and Development* 1994 8 133). This family of receptors contains serine/threonine kinase activity in their cytoplasmic domains, which are believed to be actiated by crosslinking.

The tyrosine kinases associated with activation and inactivation of transcription factors are of particular interest in providing specific pathways which can be controlled and can be used to initiate or inhibit expression of an exogenous gene.

The following table provides a number of receptors and characteristics associated with the receptor and their nuclear response elements that activate genes. The list is not exhaustive, but provides exemplary systems for use in the subject invention.

In many situations mutated cytoplasmic domains can be obtained where the signal which is transduced may vary from the wild type, resulting in a restricted or different pathway as compared to the wild-type pathway(s). For example, in the case of growth factors, such as EGF and FGF, mutations have been reported where the signal is uncoupled from cell growth but is still maintained with c-fos (Peters, *et al.*, *Nature* (1992) 358, 678).

The tyrosine kinase receptors can be found on a wide variety of cells throughout the body. In contrast, the CD3 ζ -family, the Ig family and the lymphokine β -chain receptor family are found primarily on hematopoietic cells, particularly T-cells, B-cells, mast cells, basophils, macrophages, neutrophils, and natural killer cells. The signals required for NF-AT transcription come primarily from the zeta (ζ) chain of the antigen receptor and to a lesser extent CD3 γ , δ , ϵ .

Table 1.

Ligand	DNA Element	Binding Factor(s)	Gene	Reference
Insulin and others	cAMP responsive element (cre)	LRFI	jun-B many genes	Mol. Cell Biol. (1992), 12, 4654 PNAS, 83, 3439

The cytoplasmic domain, as it exists naturally or as it may be truncated,
 5 modified or mutated, will be at least about 10, usually at least about 30 amino acids, more usually at least about 50 amino acids, and generally not more than about 400 amino acids, usually not more than about 200 amino acids. (See Romeo, *et al.*, *Cell* (1992) 68, 889-893.) While any species can be employed, the species endogenous to the host cell is usually preferred. However, in many
 10 cases, the cytoplasmic domain from a different species can be used effectively. Any of the above indicated cytoplasmic domains may be used, as well as others which are presently known or may subsequently be discovered.

For the most part, the other chimeric proteins associated with transcription factors, will differ primarily in having a cellular targeting sequence

which directs the chimeric protein to the internal side of the nuclear membrane and having transcription factors or portions thereof as the action domains. Usually, the transcription factor action domains can be divided into "DNA binding domains" and "activation domains." One can provide for a DNA
5 binding domain with one or more ligand binding domains and an activation domain with one or more ligand binding domains. In this way the DNA binding domain can be coupled to a plurality of binding domains and/or activation domains. Otherwise, the discussion for the chimeric proteins associated with the surface membrane for signal transduction is applicable to the chimeric
10 proteins for direct binding to genomic DNA. Similarly, the chimeric protein associated with exocytosis will differ primarily as to the proteins associated with fusion of the vesicle membrane with the surface membrane, in place of the transducing cytoplasmic proteins.

15 **B. Cellular Targeting Domains**

A signal peptide or sequence provides for transport of the chimeric protein to the cell surface membrane, where the same or other sequences can encode binding of the chimeric protein to the cell surface membrane. While there is a general motif of signal sequences, two or three N-terminal polar amino acids
20 followed by about 15-20 primarily hydrophobic amino acids, the individual amino acids can be widely varied. Therefore, substantially any signal peptide can be employed which is functional in the host and may or may not be associated with one of the other domains of the chimeric protein. Normally, the signal peptide is processed and will not be retained in the mature chimeric
25 protein. The sequence encoding the signal peptide is at the 5'-end of the coding sequence and will include the initiation methionine codon.

The choice of membrane retention domain is not critical to this invention, since it is found that such membrane retention domains are substantially fungible and there is no critical amino acid required for binding or bonding to
30 another membrane region for activation. Thus, the membrane retention domain can be isolated from any convenient surface membrane or cytoplasmic protein, whether endogenous to the host cell or not.

There are at least two different membrane retention domains: a transmembrane retention domain, which is an amino acid sequence which
35 extends across the membrane; and a lipid membrane retention domain, which lipid associates with the lipids of the cell surface membrane.

For the most part, for ease of construction, the transmembrane domain of the cytoplasmic domain or the receptor domain can be employed, which may tend to simplify the construction of the fused protein. However, for the lipid membrane retention domain, the processing signal will usually be added at the 5' end of the coding sequence for N-terminal binding to the membrane and, proximal to the 3' end for C-terminal binding. The lipid membrane retention domain will have a lipid of from about 12 to 24 carbon atoms, particularly 14 carbon atoms, more particularly myristoyl, joined to glycine. The signal sequence for the lipid binding domain is an N-terminal sequence and can be varied widely, usually having glycine at residue 2 and lysine or arginine at residue 7 (Kaplan, *et al.*, *Mol. Cell. Biol.* (1988) 8, 2435). Peptide sequences involving post-translational processing to provide for lipid membrane binding are described by Carr, *et al.*, *PNAS USA* (1988) 79, 6128; Aitken, *et al.*, *FEBS Lett.* (1982) 150, 314; Henderson, *et al.*, *PNAS USA* (1983) 80, 319; Schulz, *et al.*, *Virology* (1984), 123, 2131; Dellman, *et al.*, *Nature* (1985) 314, 374; and reviewed in *Ann. Rev. of Biochem.* (1988) 57, 69. An amino acid sequence of interest includes the sequence M-G-S-S-K-S-K-P-K-D-P-S-Q-R. Various DNA sequences can be used to encode such sequence in the fused receptor protein.

Generally, the transmembrane domain will have from about 18-30 amino acids, more usually about 20-30 amino acids, where the central portion will be primarily neutral, non-polar amino acids, and the termini of the domain will be polar amino acids, frequently charged amino acids, generally having about 1-2 charged, primarily basic amino acids at the termini of the transmembrane domain followed by a helical break residue, *e.g.* pro- or gly-.

C. Ligand Binding Domain

The ligand binding ("dimerization") domain of a chimeric protein of this invention can be any convenient domain which will allow for induction using a natural or unnatural ligand, preferably an unnatural synthetic ligand. The binding domain can be internal or external to the cellular membrane, depending upon the nature of the construct and the choice of ligand. A wide variety of binding proteins, including receptors, are known, including binding proteins associated with the cytoplasmic regions indicated above. Of particular interest are binding proteins for which ligands (preferably small organic ligands) are known or may be readily produced. These receptors or ligand binding domains include the FKBP's and cyclophilin receptors, the steroid receptors, the

tetracycline receptor, the other receptors indicated above, and the like, as well as "unnatural" receptors, which can be obtained from antibodies, particularly the heavy or light chain subunit, mutated sequences thereof, random amino acid sequences obtained by stochastic procedures, combinatorial syntheses, and the like. For the most part, the receptor domains will be at least about 50 amino acids, and fewer than about 350 amino acids, usually fewer than 200 amino acids, either as the natural domain or truncated active portion thereof. Preferably the binding domain will be small (<25 kDa, to allow efficient transfection in viral vectors), monomeric (this rules out the avidin-biotin system), nonimmunogenic, and should have synthetically accessible, cell permeable, nontoxic ligands that can be configured for dimerization.

The receptor domain can be intracellular or extracellular depending upon the design of the construct encoding the chimeric protein and the availability of an appropriate ligand. For hydrophobic ligands, the binding domain can be on either side of the membrane, but for hydrophilic ligands, particularly protein ligands, the binding domain will usually be external to the cell membrane, unless there is a transport system for internalizing the ligand in a form in which it is available for binding. For an intracellular receptor, the construct can encode a signal peptide and transmembrane domain 5' or 3' of the receptor domain sequence or by having a lipid attachment signal sequence 5' of the receptor domain sequence. Where the receptor domain is between the signal peptide and the transmembrane domain, the receptor domain will be extracellular.

The portion of the construct encoding the receptor can be subjected to mutagenesis for a variety of reasons. The mutagenized protein can provide for higher binding affinity, allow for discrimination by the ligand of the naturally occurring receptor and the mutagenized receptor, provide opportunities to design a receptor-ligand pair, or the like. The change in the receptor can involve changes in amino acids known to be at the binding site, random mutagenesis using combinatorial techniques, where the codons for the amino acids associated with the binding site or other amino acids associated with conformational changes can be subject to mutagenesis by changing the codon(s) for the particular amino acid, either with known changes or randomly, expressing the resulting proteins in an appropriate prokaryotic host and then screening the resulting proteins for binding. Illustrative of this situation is to modify FKBP12's Phe36 to Ala and/or Asp37 to Gly or Ala to accommodate a substituent at positions 9 or 10 of FK506 or FK520. In particular, mutant FKBP12 moieties which contain Val, Ala, Gly, Met or other small amino acids in

place of one or more of Tyr26, Phe36, Asp37, Tyr82 and Phe99 are of particular interest as receptor domains for FK506-type and FK-520-type ligands containing modifications at C9 and/or C10.

Antibody subunits, e.g. heavy or light chain, particularly fragments, more particularly all or part of the variable region, or fusions of heavy and light chain to create high-affinity binding, can be used as the binding domain. Antibodies can be prepared against haptenic molecules which are physiologically acceptable and the individual antibody subunits screened for binding affinity. The cDNA encoding the subunits can be isolated and modified by deletion of the constant region, portions of the variable region, mutagenesis of the variable region, or the like, to obtain a binding protein domain that has the appropriate affinity for the ligand. In this way, almost any physiologically acceptable haptenic compound can be employed as the ligand or to provide an epitope for the ligand. Instead of antibody units, natural receptors can be employed, where the binding domain is known and there is a useful ligand for binding.

The ability to employ in vitro mutagenesis or combinatorial modifications of sequences encoding proteins allows for the production of libraries of proteins which can be screened for binding affinity for different ligands. For example, one can totally randomize a sequence of 1 to 5, 10 or more codons, at one or more sites in a DNA sequence encoding a binding protein, make an expression construct and introduce the expression construct into a unicellular microorganism, and develop a library. One can then screen the library for binding affinity to one or desirably a plurality of ligands. The best affinity sequences which are compatible with the cells into which they would be introduced can then be used as the binding domain. The ligand would be screened with the host cells to be used to determine the level of binding of the ligand to endogenous proteins. A binding profile could be defined weighting the ratio of binding affinity to the mutagenized binding domain with the binding affinity to endogenous proteins. Those ligands which have the best binding profile could then be used as the ligand. Phage display techniques, as a non-limiting example, can be used in carrying out the foregoing.

D. Multimerization

The transduced signal will normally result from ligand-mediated oligomerization of the chimeric protein molecules, i.e. as a result of oligomerization following ligand binding, although other binding events, for example allosteric activation, can be employed to initiate a signal. The

construct of the chimeric protein will vary as to the order of the various domains and the number of repeats of an individual domain. For the extracellular receptor domain in the 5'-3' direction of transcription, the construct will encode a protein comprising the signal peptide, the receptor domain, the
5 transmembrane domain and the signal initiation domain, which last domain will be intracellular (cytoplasmic). However, where the receptor domain is intracellular, different orders may be employed, where the signal peptide can be followed by either the receptor or signal initiation domain, followed by the remaining domain, or with a plurality of receptor domains, the signal initiation
10 domain can be sandwiched between receptor domains. Usually, the active site of the signal initiation domain will be internal to the sequence and not require a free carboxyl terminus. Either of the domains can be multimerized, particularly the receptor domain, usually having not more than about 5 repeats, more usually not more than about 3 repeats.

15 For multimerizing the receptor, the ligand for the receptor domains of the chimeric surface membrane proteins will usually be multimeric in the sense that it will have at least two binding sites, with each of the binding sites capable of binding to the receptor domain. Desirably, the subject ligands will be a dimer or higher order oligomer, usually not greater than about tetrameric, of small
20 synthetic organic molecules, the individual molecules typically being at least about 150 D and fewer than about 5 kD, usually fewer than about 3 kD. A variety of pairs of synthetic ligands and receptors can be employed. For example, in embodiments involving natural receptors, dimeric FK506 can be used with an FKBP receptor, dimerized cyclosporin A can be used with the
25 cyclophilin receptor, dimerized estrogen with an estrogen receptor, dimerized glucocorticoids with a glucocorticoid receptor, dimerized tetracycline with the tetracycline receptor, dimerized vitamin D with the vitamin D receptor, and the like. Alternatively higher orders of the ligands, *e.g.* trimeric can be used. For
30 embodiments involving unnatural receptors, *e.g.* antibody subunits, modified antibody subunits or modified receptors and the like, any of a large variety of compounds can be used. A significant characteristic of these ligand units is that they bind the receptor with high affinity (preferably with a $K_d \leq 10^{-8}$ M) and are able to be dimerized chemically.

35 The ligand can have different receptor binding molecules with different epitopes (also referred to as "HED" reagents, since they can mediate hetero-dimerization or hetero-oligomerization of chimeric proteins having the same or different binding domains. For example, the ligand may comprise FK506 or an

FK506-type moiety and a CsA or a cyclosporin type moiety. Both moieties are covalently attached to a common linker moiety. Such a ligand would be useful for mediating the oligomerization of a first and second chimeric protein where the first chimeric protein contains a receptor domain such as an FKBP12 which is capable of binding to the FK506-type moiety and the second chimeric protein contains a receptor domain such as cyclophilin which is capable of binding to the cyclosporin A-type moiety.

VI. Cells

The cells may be procaryotic, but are preferably eucaryotic, including plant, yeast, worm, insect and mammalian. At present it is especially preferred that the cells be mammalian cells, particularly primate, more particularly human, but can be associated with any animal of interest, particularly domesticated animals, such as equine, bovine, murine, ovine, canine, feline, *etc.* Among these species, various types of cells can be involved, such as hematopoietic, neural, mesenchymal, cutaneous, mucosal, stromal, muscle, spleen, reticuloendothelial, epithelial, endothelial, hepatic, kidney, gastrointestinal, pulmonary, *etc.* Of particular interest are hematopoietic cells, which include any of the nucleated cells which may be involved with the lymphoid or myelomonocytic lineages. Of particular interest are members of the T- and B-cell lineages, macrophages and monocytes, myoblasts and fibroblasts. Also of particular interest are stem and progenitor cells, such as hematopoietic neural, stromal, muscle, hepatic, pulmonary, gastrointestinal, *etc.*

The cells can be autologous cells, syngeneic cells, allogenic cells and even in some cases, xenogeneic cells. The cells may be modified by changing the major histocompatibility complex ("MHC") profile, by inactivating β 2-microglobulin to prevent the formation of functional Class I MHC molecules, inactivation of Class II molecules, providing for expression of one or more MHC molecules, enhancing or inactivating cytotoxic capabilities by enhancing or inhibiting the expression of genes associated with the cytotoxic activity, or the like.

In some instances specific clones or oligoclonal cells may be of interest, where the cells have a particular specificity, such as T cells and B cells having a specific antigen specificity or homing target site specificity.

VII. Ligands

A wide variety of ligands, including both naturally occurring and synthetic substances, can be used in this invention to effect oligomerization of the chimeric protein molecules. Applicable and readily observable or measurable criteria for selecting a ligand are: (A) the ligand is physiologically acceptable (i.e., lacks undue toxicity towards the cell or animal for which it is to be used), (B) it has a reasonable therapeutic dosage range, (C) desirably (for applications in whole animals, including gene therapy applications), it can be taken orally (is stable in the gastrointestinal system and absorbed into the vascular system), (D) it can cross the cellular and other membranes, as necessary, and (E) binds to the receptor domain with reasonable affinity for the desired application. A first desirable criterion is that the compound is relatively physiologically inert, but for its activating capability with the receptors. The less the ligand binds to native receptors and the lower the proportion of total ligand which binds to nature receptors, the better the response will normally be. Particularly, the ligand should not have a strong biological effect on native proteins. For the most part, the ligands will be non-peptide and non-nucleic acid.

The subject compounds will for the most part have two or more units, where the units can be the same or different, joined together through a central linking group. The "units" will be individual moieties (e.g., FK506, FK520, cyclosporin A, a steroid, etc.) capable of binding the receptor domain. Each of the units will usually be joined to the linking group through the same reactive moieties, at least in homodimers or higher order homo-oligomers.

As indicated above, there are a variety of naturally-occurring receptors for small non-proteinaceous organic molecules, which small organic molecules fulfill the above criteria, and can be dimerized at various sites to provide a ligand according to the subject invention. Substantial modifications of these compounds are permitted, so long as the binding capability is retained and with the desired specificity. Many of the compounds will be macrocyclics, e.g. macrolides. Suitable binding affinities will be reflected in K_d values well below 10^{-4} , preferably below 10^{-6} , more preferably below about 10^{-7} , although binding affinities below 10^{-9} or 10^{-10} are possible, and in some cases will be most desirable.

Currently preferred ligands comprise oligomers, usually dimers, of compounds capable of binding to an FKBP protein and/or to a cyclophilin protein. Such ligands includes homo- and heteromultimers (usually 2-4, more

usually 2-3 units) of cyclosporin A, FK506, FK520, and rapamycin, and derivatives thereof, which retain their binding capability to the natural or mutagenized binding domain. Many derivatives of such compounds are already known, including synthetic high affinity FKBP ligands, which can be used in the practice of this invention. See e.g. Holt et al, J Am Chem Soc 1993, 115, 9925-9935. Sites of interest for linking of FK506 and analogs thereof include positions involving annular carbon atoms from about 17 to 24 and substituent positions bound to those annular atoms, e.g. 21 (allyl), 22, 37, 38, 39 and 40, or 32 (cyclohexyl), while the same positions except for 21 are of interest for FK520. For cyclosporin, sites of interest include MeBmt, position 3 and position 8.

Of particular interest are modifications to the ligand which change its binding characteristics, particularly with respect to the ligand's naturally occurring receptor. Concomitantly, one would change the binding protein to accommodate the change in the ligand. For example, one can modify the groups at position 9 or 10 of FK506 (see Van Duyne *et al* (1991) *Science* 252, 839), so as to increase their steric requirement, by replacing the hydroxyl with a group having greater steric requirements, or by modifying the carbonyl at position 10, replacing the carbonyl with a group having greater steric requirements or functionalizing the carbonyl, e.g. forming an N-substituted Schiff's base or imine, to enhance the bulk at that position. Various functionalities which can be conveniently introduced at those sites are alkyl groups to form ethers, acylamido groups, N-alkylated amines, where a 2-hydroxyethylimine can also form a 1,3-oxazoline, or the like. Generally, the substituents will be from about 1 to 6, usually 1 to 4, and more usually 1 to 3 carbon atoms, with from 1 to 3, usually 1 to 2 heteroatoms, which will usually be oxygen, sulfur, nitrogen, or the like. By using different derivatives of the basic structure, one can create different ligands with different conformational requirements for binding. By mutagenizing receptors, one can have different receptors of substantially the same sequence having different affinities for modified ligands not differing significantly in structure.

Other ligands which can be used are steroids. The steroids can be oligomerized, so that their natural biological activity is substantially diminished without loss of their binding capability with respect to a chimeric protein containing one or more steroid receptor domains. By way of non-limiting example, glucocorticoids and estrogens can be so used. Various drugs can also be used, where the drug is known to bind to a particular receptor with high affinity. This is particularly so where the binding domain of the receptor is

known, thus permitting the use in chimeric proteins of this invention of *only* the binding domain, rather than the entire native receptor protein. For this purpose, enzymes and enzyme inhibitors can be used.

5 **A. Linkers**

Various functionalities can be involved in the linking, such as amide groups, including carbonic acid derivatives, ethers, esters, including organic and inorganic esters, amino, or the like. To provide for linking, the particular monomer can be modified by oxidation, hydroxylation, substitution, reduction,
10 *etc.*, to provide a site for coupling. Depending on the monomer, various sites can be selected as the site of coupling.

The multimeric ligands can be synthesized by any convenient means, where the linking group will be at a site which does not interfere with the binding of the binding site of a ligand to the receptor. Where the active site for
15 physiological activity and binding site of a ligand to the receptor domain are different, it will usually be desirable to link at the active site to inactivate the ligand. Various linking groups can be employed, usually of from 1-30, more usually from about 1-20 atoms in the chain between the two molecules (other than hydrogen), where the linking groups will be primarily composed of carbon,
20 hydrogen, nitrogen, oxygen, sulphur and phosphorous. The linking groups can involve a wide variety of functionalities, such as amides and esters, both organic and inorganic, amines, ethers, thioethers, disulfides, quaternary ammonium salts, hydrazines, *etc.* The chain can include aliphatic, alicyclic, aromatic or heterocyclic groups. The chain will be selected based on ease of synthesis and
25 the stability of the multimeric ligand. Thus, if one wishes to maintain long-term activity, a relatively inert chain will be used, so that the multimeric ligand link will not be cleaved. Alternatively, if one wishes only a short half-life in the blood stream, then various groups can be employed which are readily cleaved, such as esters and amides, particularly peptides, where circulating and/or
30 intracellular proteases can cleave the linking group.

Various groups can be employed as the linking group between ligands, such as alkylene, usually of from 2 to 20 carbon atoms, azalkylene (where the nitrogen will usually be between two carbon atoms), usually of from 4 to 18 carbon atoms), N-alkylene azalkylene (see above), usually of from 6 to 24
35 carbon atoms, arylene, usually of from 6 to 18 carbon atoms, ardiakylene, usually of from 8 to 24 carbon atoms, bis-carboxamido alkylene of from about 8 to 36 carbon atoms, *etc.* Illustrative groups include decylene, octadecylene, 3-

azapentylene, 5-azadecylene, N-butylene 5-azanonylene, phenylene, xylylene, p-dipropylenebenzene, bis-benzoyl 1,8-diaminooctane and the like. Multivalent or other (see below) ligand molecules containing linker moieties as described above can be evaluated with chimeric proteins of this invention bearing
5 corresponding receptor domains using materials and methods described in the examples which follow.

B. Ligand Characteristics

For intracellular binding domains, the ligand will be selected to be able to
10 be transferred across the membrane in a bioactive form, that is, it will be membrane permeable. Various ligands are hydrophobic or can be made so by appropriate modification with lipophilic groups. Particularly, the linking bridge can serve to enhance the lipophilicity of the ligand by providing aliphatic side chains of from about 12 to 24 carbon atoms. Alternatively, one or more groups
15 can be provided which will enhance transport across the membrane, desirably without endosome formation.

In some instances, multimeric ligands need not be employed. For example, molecules can be employed where two different binding sites provide for dimerization of the receptor. In other instances, binding of the ligand can
20 result in a conformational change of the receptor domain, resulting in activation, e.g. oligomerization, of the receptor. Other mechanisms may also be operative for inducing the signal, such as binding a single receptor with a change in conformation resulting in activation of the cytoplasmic domain.

25 C. Ligand Antagonists

Monomeric ligands can be used for reversing the effect of the multimeric ligand, i.e., for inhibiting or disrupting oligomer formation or maintenance. Thus, if one wishes to rapidly terminate the effect of cellular activation, a monomeric ligand can be used. Conveniently, the parent ligand moiety can be modified at
30 the same site as the multimer, using the same procedure, except substituting a monofunctional compound for the polyfunctional compound. Instead of the polyamines, monoamines, particularly of from 2 to 20 (although they can be longer), and usually 2 to 12, carbon atoms can be used, such as ethylamine, hexylamine, benzylamine, *etc.* Alternatively, the monovalent parent compound
35 can be used, in cases in which the parent compound does not have undue undesirable physiological activity (e.g. immunosuppression, mitogenesis, toxicity, *etc.*)

D. Illustrative hetero-oligomerizing (HED) and homo-oligomerizing (HOD) reagents with "bumps" that can bind to mutant receptors containing compensatory mutations

5

As discussed above, one can prepare modified HED/HOD reagents that will fail to bind appreciably to their wildtype receptors (e.g., FKBP12) due to the presence of substituents ("bumps") on the reagents that sterically clash with sidechain residues in the receptor's binding pocket. One may also make
10 corresponding receptors that contain mutations at the interfering residues ("compensatory mutations") and therefore gain the ability to bind ligands with bumps. Using "bumped" ligand moieties and receptor domains bearing compensatory mutations should enhance the specificity and thus the potency of
15 our reagents. Bumped reagents should not bind to the endogenous, wildtype receptors, which can otherwise act as a "buffer" toward dimerizers based on natural ligand moieties. In addition, the generation of novel receptor-ligand pairs should simultaneously yield the HED reagents that will be used when heterodimerization is required. For example, regulated vesicle fusion may be
20 achieved by inducing the heterodimerization of syntaxin (a plasma membrane fusion protein) and synaptobrevin (a vesicle membrane fusion protein) using a HED reagent. This would not only provide a research tool, but could also serve as the basis of a gene therapy treatment for diabetes, using appropriately modified secretory cells.

As an illustration of "Bumped FK1012s" we prepared C10 acetamide
25 and formamide derivatives of FK506. See Figure 16A and our report, Spencer et al, "Controlling Signal Transduction with Synthetic Ligands," *Science* 262 5136 (1993): 1019-1024 for additional details concerning the syntheses of FK1012s A-C and FK506M. We chose to create two classes of bumped FK1012s: one with a bump at C10 and one at C9. The R- and S-isomers of the C10 acetamide
30 and formamide of FK506 have been synthesized according to the reaction sequence in Figure 05B. These bumped derivatives have lost at least three orders of magnitude in their binding affinity towards FKBP12 (Figure 16B). The affinities were determined by measuring the ability of the derivatives to inhibit FKBP12's rotamase activity.

35 An illustrative member of a second class of C9-bumped derivatives is the spiro-epoxide (depicted in Figure 16C), which has been prepared by adaptation of known procedures. See e.g. Fisher et al, *J Org Chem* 56 8(1991):

2900-7 and Edmunds et al, *Tet Lett* 32 48 (1991):819-820. A particularly interesting series of C9 derivatives are characterized by their sp³ hybridization and reduced oxidation state at C9. Several such compounds have been synthesized according to the reactions shown in Figure 16C.

5 It should be appreciated that heterodimers (and other hetero-oligomerizers) must be constructed differently than the homodimers, at least for applications where homodimer contamination could adversely affect their successful use. One illustrative synthetic strategy developed to overcome this problem is outlined in Figure 16D. Coupling of mono alloc-protected 1,6-
10 hexanediamine (Stahl et al, *J Org Chem* 43 11 (1978): 2285-6) with a derivatized form of FK506 in methylene chloride with an excess of triethylamine gave an alloc-amine-substituted FK506 in 44% yield. This intermediate can now be used in the coupling with any activated FK506 (or bumped-FK506) molecule. Deprotection with catalytic tetrakis-triphenylphosphine palladium in the
15 presence of dimedone at rt in THF removes the amine protecting group. Immediate treatment with an activated FK506 derivative, followed by desilylation leads to a dimeric product. This technique has been used to synthesize the illustrated HOD and HED reagents.

20 **E. Illustrative Cyclosporin-based reagents**

Cyclosporin A (CsA) is a cyclic undecapeptide that binds with high affinity (6nM) to its intracellular receptor cyclophilin, an 18 kDa monomeric protein. The resulting complex, like the FKBP12-FK506 complex, binds to and
25 inactivates the protein phosphatase calcineurin resulting in the immunosuppressive properties of the drug. As a further illustration of this invention, we have dimerized CsA via its MeBmt1 sidechain in 6 steps and 35% overall yield to give (CsA)₂ (Figure 17, steps 1-4 were conducted as reported in Eberle et al, *J Org Chem* 57 9 (1992): 2689-91). As with FK1012s, the site for
30 dimerization was chosen such that the resulting dimer can bind to two molecules of cyclophilin yet cannot bind to calcineurin following cyclophilin-binding. We have demonstrated that (CsA)₂ binds to cyclophilin A with 1:2 stoichiometry. Hence, (CsA)₂, like FK1012s, does not inhibit signaling pathways and is thus neither immunosuppressive nor toxic.

VIII. Target Gene

A. Transcription Initiation Region

The second construct or second series of constructs will have a responsive element in the 5' region, which responds to ligand-mediated oligomerization of the chimeric receptor protein, presumably via the generation and transduction of a transcription initiation signal as discussed *infra*. Therefore, it will be necessary to know at least one transcription initiation system, e.g. factor, which is activated either directly or indirectly, by the cytoplasmic domain or can be activated by association of two domains. It will also be necessary to know at least one promoter region which is responsive to the resulting transcription initiation system. Either the promoter region or the gene under its transcriptional control need be known. In other words, an action domain can be selected for the chimeric proteins (encoded by a "first" series construct) based on the role of that action domain in initiating transcription via a given promoter or responsive element. See e.g. Section V(A) "Cytoplasmic domains", above.

Where the responsive element is known, it can be included in the target gene construct to provide an expression cassette for integration into the genome (whether episomally or by chromosomal incorporation). It is not necessary to have isolated the particular sequence of the responsive element, so long as a gene is known which is transcriptionally activated by the cytoplasmic domain upon natural ligand binding to the protein comprising the cytoplasmic domain. Homologous recombination could then be used for insertion of the gene of interest downstream from the promoter region to be under the transcriptional regulation of the endogenous promoter region. Where the specific responsive element sequence is known, that can be used in conjunction with a different transcription initiation region, which can have other aspects, such as a high or low activity as to the rate of transcription, binding of particular transcription factors and the like.

The expression construct will therefore have at its 5' end in the direction of transcription, the responsive element and the promoter sequence which allows for induced transcription initiation of a target gene of interest, usually a therapeutic gene. The transcriptional termination region is not as important, and can be used to enhance the lifetime of or make short half-lived mRNA by inserting AU sequences which serve to reduce the stability of the mRNA and, therefore, limit the period of action of the protein. Any region can be employed

which provides for the necessary transcriptional termination, and as appropriate, translational termination.

The responsive element can be a single sequence or can be oligomerized, usually having not more than about 5 repeats, usually having about 3 repeats.

- 5 Homologous recombination can also be used to remove or inactivate endogenous transcriptional control sequences, including promoter and/or responsive elements, which are responsive to the oligomerization event, and/or to insert such responsive transcriptional control sequences upstream of a desired endogenous gene.

10

B. Product

- A wide variety of genes can be employed as the target gene, including genes that encode a protein of interest or an antisense sequence of interest or a ribozyme of interest. The target gene can be any sequence of interest which provides a desired phenotype. The target gene can express a surface membrane protein, a secreted protein, a cytoplasmic protein, or there can be a plurality of target genes which can express different types of products. The target gene may be an antisense sequence which can modulate a particular pathway by inhibiting a transcriptional regulation protein or turn on a particular pathway by inhibiting the translation of an inhibitor of the pathway. The target gene can encode a ribozyme which may modulate a particular pathway by interfering, at the RNA level, with the expression of a relevant transcriptional regulator or with the expression of an inhibitor of a particular pathway. The proteins which are expressed, singly or in combination, can involve homing, cytotoxicity, proliferation, immune response, inflammatory response, clotting or dissolving of clots, hormonal regulation, or the like. The proteins expressed could be naturally-occurring, mutants of naturally-occurring proteins, unique sequences, or combinations thereof.
- 15
20
25

- The gene can be any gene which is secreted by a cell, so that the encoded product can be made available at will, whenever desired or needed by the host. Various secreted products include hormones, such as insulin, human growth hormone, glucagon, pituitary releasing factor, ACTH, melanotropin, relaxin, *etc.*; growth factors, such as EGF, IGF-1, TGF- α , - β , PDGF, G-CSF, M-CSF, GM-CSF, FGF, erythropoietin, megakaryocytic stimulating and growth factors, *etc.*; interleukins, such as IL-1 to -13; TNF- α and - β , *etc.*; and enzymes, such as tissue plasminogen activator, members of the complement cascade, perforins, superoxide dismutase, coagulation factors, antithrombin-III, Factor VIIIc, Factor
- 30
35

VIIIvW, α -anti-trypsin, protein C, protein S, endorphins, dynorphin, bone morphogenetic protein, CFTR, *etc.*

The gene can be any gene which is naturally a surface membrane protein or made so by introducing an appropriate signal peptide and transmembrane sequence. Various proteins include homing receptors, *e.g.* L-selectin (Mel-14), blood-related proteins, particularly having a kringle structure, *e.g.* Factor VIIIc, Factor VIIIvW, hematopoietic cell markers, *e.g.* CD3, CD4, CD8, B cell receptor, TCR subunits α , β , γ , δ , CD10, CD19, CD28, CD33, CD38, CD41, *etc.*, receptors, such as the interleukin receptors IL-2R, IL-4R, *etc.*, channel proteins, for influx or efflux of ions, *e.g.* H^+ , Ca^{+2} , K^+ , Na^+ , Cl^- , *etc.*, and the like; CFTR, tyrosine activation motif, ζ activation protein, *etc.*

Proteins may be modified for transport to a vesicle for exocytosis. By adding the sequence from a protein which is directed to vesicles, where the sequence is modified proximal to one or the other terminus, or situated in an analogous position to the protein source, the modified protein will be directed to the Golgi apparatus for packaging in a vesicle. This process in conjunction with the presence of the chimeric proteins for exocytosis allows for rapid transfer of the proteins to the extracellular medium and a relatively high localized concentration.

Also, intracellular proteins can be of interest, such as proteins in metabolic pathways, regulatory proteins, steroid receptors, transcription factors, *etc.*, particularly depending upon the nature of the host cell. Some of the proteins indicated above can also serve as intracellular proteins.

The following are a few illustrations of different genes. In T-cells, one may wish to introduce genes encoding one or both chains of a T-cell receptor. For B-cells, one could provide the heavy and light chains for an immunoglobulin for secretion. For cutaneous cells, *e.g.* keratinocytes, particularly stem cells keratinocytes, one could provide for infectious protection, by secreting α -, β - or γ -interferon, antichemotactic factors, proteases specific for bacterial cell wall proteins, *etc.*

In addition to providing for expression of a gene having therapeutic value, there will be many situations where one may wish to direct a cell to a particular site. The site can include anatomical sites, such as lymph nodes, mucosal tissue, skin, synovium, lung or other internal organs or functional sites, such as clots, injured sites, sites of surgical manipulation, inflammation, infection, *etc.* By providing for expression of surface membrane proteins which will direct the host cell to the particular site by providing for binding at the host

target site to a naturally-occurring epitope, localized concentrations of a secreted product can be achieved. Proteins of interest include homing receptors, *e.g.* L-selectin, GMP140, CLAM-1, *etc.*, or addressins, *e.g.* ELAM-1, PNA_d, LNA_d, *etc.*, clot binding proteins, or cell surface proteins that respond to localized gradients of chemotactic factors. There are numerous situations where one would wish to direct cells to a particular site, where release of a therapeutic product could be of great value.

In many situations one may wish to be able to kill the modified cells, where one wishes to terminate the treatment, the cells become neoplastic, in research where the absence of the cells after their presence is of interest, or other event. For this purpose one can provide for the expression of the Fas antigen or TNF receptor fused to a binding domain. (Watanabe-Fukunaga et al. Nature (1992) 356, 314-317) In the original modification, one can provide for constitutive expression of such constructs, so that the modified cells have such proteins on their surface or present in their cytoplasm. Alternatively, one can provide for controlled expression, where the same or different ligand can initiate expression and initiate apoptosis. By providing for the cytoplasmic portions of the Fas antigen or TNF receptor in the cytoplasm joined to binding regions different from the binding regions associated with expression of a target gene of interest, one can kill the modified cells under controlled conditions.

C. Illustrative Exemplifications

By way of illustration, cardiac patients or patients susceptible to stroke may be treated as follows. Cells modified as described herein may be administered to the patient and retained for extended periods of time. Illustrative cells include plasma cells, B-cells, T-cells, or other hematopoietic cells. The cell would be modified to express a protein which binds to a blood clot, *e.g.* having a kringle domain structure or an adhesive interactive protein, *e.g.* CD41, and to express a clot dissolving protein, *e.g.* tissue plasminogen activator, streptokinase, *etc.* In this way, upon ligand-mediated oligomerization, the cells would accumulate at the site of the clot and provide for a high localized concentration of the thrombolytic protein.

Another example is reperfusion injury. Cells of limited lifetime could be employed, *e.g.* macrophages or polymorphonuclear leukocytes ("neutrophils"). The cells would have a neutrophil homing receptor to direct the cells to a site of reperfusion injury. The cell would also express superoxide dismutase, to destroy singlet oxygen and inhibit radical attack on the tissue.

A third example is autoimmune disease. Cells of extended lifetime, *e.g.* T cells could be employed. The constructs would provide for a homing receptor for homing to the site of autoimmune injury and for cytotoxic attack on cells causing the injury. The therapy would then be directed against cells causing the injury. Alternatively, one could provide for secretion of soluble receptors or other peptide or protein, where the secretion product would inhibit activation of the injury causing cells or induce anergy. Another alternative would be to secrete an antiinflammatory product, which could serve to diminish the degenerative effects.

A fourth example involves treatment of chronic pain with endorphin via encapsulation. A stock of human fibroblasts is transfected with a construct in which the chimeric transcriptional regulatory protein controls the transcription of human endorphin. The DNA construct consists of three copies of the binding site for the HNF-1* transcription factor GTTAAGTTAAC upstream of a TATAAA site and a transcriptional initiation site. The endorphin cDNA would be inserted downstream of the initiation site and upstream of a polyadenylation and termination sequences. Optionally, the endorphin cDNA is outfitted with "PEST" sequences to make the protein unstable or AUUA sequences in the 3' nontranslated region of the mRNA to allow it to be degraded quickly.

The fibroblasts are also transfected with a construct having two transcription units, one of which would encode the HNF-1* cDNA truncated to encode just the DNA binding sequences from amino acids 1 to 250 coupled to a trimeric FKBP binding domain under the transcriptional and translational control of regulatory initiation and termination regions functional in the fibroblasts. The construct would include an additional transcription unit driven by the same regulatory regions directing the production of a transcriptional activation domain derived from HNF-4 coupled to trimeric FKBP'. (The prime intends an altered FKBP that binds at nM concentration to a modified FK506. The modification inhibits binding to the endogenous FKBP.)

These genetically modified cells would be encapsulated to inhibit immune recognition and placed under the patient's skin or other convenient internal site. When the patient requires pain medication, the patient administers a dimeric ligand FK506-FK506', where about 1 µg to 1 mg would suffice. In this manner one could provide pain relief without injections or the danger of addiction.

A fifth example is the treatment of osteoporosis. Lymphocytes can be clonally developed or skin fibroblasts grown in culture from the patient to be

treated. The cells would be transfected as described above, where a bone morphogenic factor cDNA gene would replace the endorphin gene. For lymphocytes, antigen specific clones could be used which would allow their destruction with antibodies to the idiotype of the sIg. In addition, administration of the antigen for the sIg would expand the cell population to increase the amount of the protein which could be delivered. The lymphocyte clones would be infused and the ligand administered as required for production of the bone morphogenic factor. By monitoring the response to the ligand, one could adjust the amount of bone morphogenic factor which is produced, so as to adjust the dosage to the required level.

A sixth situation has general application in conjunction with gene therapies involving cells which may be required to be destroyed. For example, a modified cell may become cancerous or result in another pathologic state. Constructs would be transfected into the modified cells having the necessary transcriptional and translational regulatory regions and encoding a protein which upon oligomerization results in cell death, e.g. apoptosis. For example, the fas antigen or Apo-1 antigen induces apoptosis in most cell types (Trauth et al. (1989) Science 245, 301-305; Watanaba-Fukunaga et al. (1992) Nature 356, 314) In this manner by co-transfecting the protective constructs into cells used for gene therapy or other purpose, where there may be a need to ensure the death of a portion or all of the cells, the cells may be modified to provide for controlled cytotoxicity by means of the ligand.

Another situation is to modify antigen specific T cells, where one can activate expression of a protein product to activate the cells. The T cell receptor could be directed against tumor cells, pathogens, cells mediating autoimmunity, and the like. By providing for activation of the cells, for example, an interleukin such as IL-2, one could provide for expansion of the modified T cells in response to a ligand. Other uses of the modified T cells would include expression of homing receptors for directing the T cells to specific sites, where cytotoxicity, upregulation of a surface membrane protein of target cells, e.g. endothelial cells, or other biological event would be desired.

Alternatively one may want to deliver high doses of cytotoxic factors to the target site. For example, upon recognition of tumor antigens via a homing receptor, tumor-infiltrating lymphocytes (TILs) may be triggered to deliver toxic concentrations of TNF or other similar product.

Another alternative is to export hormones or factors which are exocytosed. By providing for enhanced exocytosis, a greater amount of the

hormone, or factor will be exported; in addition, if there is a feedback mechanism based on the amount of the hormone or factor in the cytoplasm, increased production of the hormone or factor will result. Or, one may provide for induced expression of the hormone or factor, so that expression and export may be induced concomitantly.

One may also provide for proteins in retained body fluids, *e.g.* vascular system, lymph system, cerebrospinal fluid; *etc.* By modifying cells which can have an extended lifetime in the host, *e.g.* hematopoietic cells, keratinocytes, muscle cells, *etc.* particularly, stem cells, the proteins can be maintained in the fluids for extended periods of time. The cells may be modified with constructs which provide for secretion or endocytosis. The constructs for secretion would have as the translocation domain, a signal peptide, and then as in the case of the other chimeric proteins, a binding domain and an action domain. The action domains may be derived from the same or different proteins. For example, with tissue plasminogen activator, one could have the clot binding region as one action domain and the plasminogen active site as a different action domain. Alternatively, one could provide enhanced blockage of homing, by having a binding protein, such as LFA-1 as one action domain and a selection as a second action domain. By modifying subunits of proteins, *e.g.* integrins, T-cell receptor, *slg*, or the like, one could provide soluble forms of surface membrane proteins which could be brought together to bind to a molecule. Other opportunities are complement proteins, platelet membrane proteins involved in clotting, autoantigens on the surface of cells, and pathogenic molecules on the surface of infectious agents.

25

IX. Introduction of Constructs into Cells

The constructs can be introduced as one or more DNA molecules or constructs, where there will usually be at least one marker and there may be two or more markers, which will allow for selection of host cells which contain the construct(s). The constructs can be prepared in conventional ways, where the genes and regulatory regions may be isolated, as appropriate, ligated, cloned in an appropriate cloning host, analyzed by restriction or sequencing, or other convenient means. Particularly, using PCR, individual fragments including all or portions of a functional unit may be isolated, where one or more mutations may be introduced using "primer repair", ligation, *in vitro* mutagenesis, *etc.* as appropriate. The construct(s) once completed and demonstrated to have the appropriate sequences may then be introduced into the host cell by any

30
35

convenient means. The constructs may be integrated and packaged into non-replicating, defective viral genomes like Adenovirus, Adeno-associated virus (AAV), or Herpes simplex virus (HSV) or others, including retroviral vectors, for infection or transduction into cells. The constructs may include viral sequences for transfection, if desired. Alternatively, the construct may be introduced by fusion, electroporation, biolistics, transfection, lipofection, or the like. The host cells will usually be grown and expanded in culture before introduction of the construct(s), followed by the appropriate treatment for introduction of the construct(s) and integration of the construct(s). The cells will then be expanded and screened by virtue of a marker present in the construct. Various markers which may be used successfully include *hprt*, neomycin resistance, thymidine kinase, hygromycin resistance, *etc.*

In some instances, one may have a target site for homologous recombination, where it is desired that a construct be integrated at a particular locus. For example, can knock-out an endogenous gene and replace it (at the same locus or elsewhere) with the gene encoded for by the construct using materials and methods as are known in the art for homologous recombination. Alternatively, instead of providing a gene, one may modify the transcriptional initiation region of an endogenous gene to be responsive to the signal initiating domain. In such embodiments, transcription of an endogenous gene such as EPO, tPA, SOD, or the like, would be controlled by administration of the ligand. For homologous recombination, one may use either Ω or O-vectors. See, for example, Thomas and Capecchi, *Cell* (1987) 51, 503-512; Mansour, *et al.*, *Nature* (1988) 336, 348-352; and Joyner, *et al.*, *Nature* (1989) 338, 153-156.

The constructs may be introduced as a single DNA molecule encoding all of the genes, or different DNA molecules having one or more genes. The constructs may be introduced simultaneously or consecutively, each with the same or different markers. In an illustrative example, one construct would contain a therapeutic gene under the control of a specific responsive element (e.g. NFAT), another encoding the receptor fusion protein comprising the signaling region fused to the ligand receptor domain (e.g. as in MZF3E). A third DNA molecule encoding a homing receptor or other product that increases the efficiency of delivery of the therapeutic product may also be introduced.

Vectors containing useful elements such as bacterial or yeast origins of replication, selectable and/or amplifiable markers, promoter/enhancer elements for expression in procaryotes or eucaryotes, *etc.* which may be used to prepare stocks of construct DNAs and for carrying out transfections are well known in

the art, and many are commercially available.

X. Administration of Cells and Ligands

The cells which have been modified with the DNA constructs are then
5 grown in culture under selective conditions and cells which are selected as
having the construct may then be expanded and further analyzed, using, for
example, the polymerase chain reaction for determining the presence of the
construct in the host cells. Once the modified host cells have been identified,
they may then be used as planned, e.g. grown in culture or introduced into a
10 host organism.

Depending upon the nature of the cells, the cells may be introduced into
a host organism, e.g. a mammal, in a wide variety of ways. Hematopoietic cells
may be administered by injection into the vascular system, there being usually at
least about 10^4 cells and generally not more than about 10^{10} , more usually not
15 more than about 10^8 cells. The number of cells which are employed will depend
upon a number of circumstances, the purpose for the introduction, the lifetime of
the cells, the protocol to be used, for example, the number of administrations,
the ability of the cells to multiply, the stability of the therapeutic agent, the
physiologic need for the therapeutic agent, and the like. Alternatively, with skin
20 cells which may be used as a graft, the number of cells would depend upon the
size of the layer to be applied to the burn or other lesion. Generally, for
myoblasts or fibroblasts, the number of cells will at least about 10^4 and not
more than about 10^8 and may be applied as a dispersion, generally being
injected at or near the site of interest. The cells will usually be in a
25 physiologically-acceptable medium.

Instead of *ex vivo* modification of the cells, in many situations one may
wish to modify cells *in vivo*. For this purpose, various techniques have been
developed for modification of target tissue and cells *in vivo*. A number of virus
vectors have been developed, such as adenovirus and retroviruses, which allow
30 for transfection and random integration of the virus into the host. See, for
example, Dubensky et al. (1984) Proc. Natl. Acad. Sci. USA 81, 7529-7533;
Kaneda et al., (1989) Science 243,375-378; Hiebert et al. (1989) Proc. Natl.
Acad. Sci. USA 86, 3594-3598; Hatzoglou et al. (1990) J. Biol. Chem. 265, 17285-
17293 and Ferry, et al. (1991) Proc. Natl. Acad. Sci. USA 88, 8377-8381. The
35 vector may be administered by injection, e.g. intravascularly or intramuscularly,
inhalation, or other parenteral mode.

In accordance with *in vivo* genetic modification, the manner of the modification will depend on the nature of the tissue, the efficiency of cellular modification required, the number of opportunities to modify the particular cells, the accessibility of the tissue to the DNA composition to be introduced, and the like. By employing an attenuated or modified retrovirus carrying a target transcriptional initiation region, if desired, one can activate the virus using one of the subject transcription factor constructs, so that the virus may be produced and transfect adjacent cells.

The DNA introduction need not result in integration in every case. In some situations, transient maintenance of the DNA introduced may be sufficient. In this way, one could have a short term effect, where cells could be introduced into the host and then turned on after a predetermined time, for example, after the cells have been able to home to a particular site.

The ligand providing for activation of the cytoplasmic domain may then be administered as desired. Depending upon the binding affinity of the ligand, the response desired, the manner of administration, the half-life, the number of cells present, various protocols may be employed. The ligand may be administered parenterally or orally. The number of administrations will depend upon the factors described above. The ligand may be taken orally as a pill, powder, or dispersion; buccally; sublingually; injected intravascularly, intraperitoneally, subcutaneously; by inhalation, or the like. The ligand (and monomeric compound) may be formulated using conventional methods and materials well known in the art for the various routes of administration. The precise dose and particular method of administration will depend upon the above factors and be determined by the attending physician or human or animal healthcare provider. For the most part, the manner of administration will be determined empirically.

In the event that the activation by the ligand is to be reversed, the monomeric compound may be administered or other single binding site compound which can compete with the ligand. Thus, in the case of an adverse reaction or the desire to terminate the therapeutic effect, the monomeric binding compound can be administered in any convenient way, particularly intravascularly, if a rapid reversal is desired. Alternatively, one may provide for the presence of an inactivation domain with a DNA binding domain, or apoptosis by having Fas or TNF receptor present as constitutively expressed constructs.

The particular dosage of the ligand for any application may be

determined in accordance with the procedures used for therapeutic dosage monitoring, where maintenance of a particular level of expression is desired over an extended period of times, for example, greater than about two weeks, or where there is repetitive therapy, with individual or repeated doses of ligand
5 over short periods of time, with extended intervals, for example, two weeks or more. A dose of the ligand within a predetermined range would be given and monitored for response, so as to obtain a time-expression level relationship, as well as observing therapeutic response. Depending on the levels observed during the time period and the therapeutic response, one could provide a larger
10 or smaller dose the next time, following the response. This process would be iteratively repeated until one obtained a dosage within the therapeutic range. Where the ligand is chronically administered, once the maintenance dosage of the ligand is determined, one could then do assays at extended intervals to be assured that the cellular system is providing the appropriate response and level
15 of the expression product.

It should be appreciated that the system is subject to many variables, such as the cellular response to the ligand, the efficiency of expression and, as appropriate, the level of secretion, the activity of the expression product, the particular need of the patient, which may vary with time and circumstances, the
20 rate of loss of the cellular activity as a result of loss of cells or expression activity of individual cells, and the like. Therefore, it is expected that for each individual patient, even if there were universal cells which could be administered to the population at large, each patient would be monitored for the proper dosage for the individual.

25 The subject methodology and compositions may be used for the treatment of a wide variety of conditions and indications. For example, B- and T-cells may be used in the treatment of cancer, infectious diseases, metabolic deficiencies, cardiovascular disease, hereditary coagulation deficiencies, autoimmune diseases, joint degenerative diseases, *e.g.* arthritis, pulmonary
30 disease, kidney disease, endocrine abnormalities, *etc.* Various cells involved with structure, such as fibroblasts and myoblasts, may be used in the treatment of genetic deficiencies, such as connective tissue deficiencies, arthritis, hepatic disease, *etc.* Hepatocytes could be used in cases where large amounts of a protein must be made to complement a deficiency or to deliver a therapeutic
35 product to the liver or portal circulation.

The following examples are offered by way illustration and not by way limitation.

Examples

5 Cellular Transformations and Evaluation

Example 1: Induction of Isolated IL-2 Enhancer-Binding Transcription Factors by Cross-Linking the CD3 Chain of the T-Cell Receptor.

10 The plasmid pSXNeo/IL2 (IL2-SX) (Fig. 1), which contains the placental secreted alkaline phosphatase gene under the control of human IL-2 promoter (-325 to +47; MCB(86) 6, 3042), and related plasmid variants (*i.e.* NFAT-SX, NF B-SX, OAP/Oct1-SX, and AP-1-SX) in which the reporter gene is under the transcriptional control of the minimal IL-2 promoter (-325 to -294 and -72 to

15 +47) combined with synthetic oligomers containing various promoter elements (*i.e.* NFAT, NK B, OAP/Oct-1, and AP1, respectively), were made by three piece ligations of 1) pPL/SEAP (Berger, *et al.*, *Gene* (1988) 66,1) cut with SspI and HindIII; 2) pSV2/Neo (Southern and Berg, *J. Mol. Appl. Genet.* (1982) 1, 332) cut with NdeI, blunted with Klenow, then cut with PvuI; and 3) various

20 promoter-containing plasmids (*i.e.* NFAT-CD8, B-CD8, cx12lacZ-Oct-1, AP1-LUCIF3H, or cx15IL2) (described below) cut with PvuI and HindIII. NFAT-CD8 contains 3 copies of the NFAT-binding site (-286 to -257; *Genes and Dev.* (1990) 4, 1823) and cx12lacZ-Oct contains 4 copies of the OAP/Oct-1/(ARRE-1) binding site (MCB, (1988) 8, 1715) from the human IL-2 enhancer; B-CD8

25 contains 3 copies of the NF B binding site from the murine light chain (EMBO (1990) 9, 4425) and AP1-LUCIF3H contains 5 copies of the AP-1 site (5'-TGA-CTCAGCGC-3') from the metallothionein promoter.

In each transfection, 5 µg of expression vector, pCDL-SR (MCB 8, 466-72) (Tac-IL2 receptor -chain), encoding the chimeric receptor TAC/TAC/Z

30 (TTZ) (PNAS 88, 8905-8909), was co-transfected along with various secreted alkaline phosphatase-based reporter plasmids (see map of pSXNeo/IL2 in Fig. 1) in TAg Jurkat cells (a derivative of the human T-cell leukemia line Jurkat stably transfected with the SV40 large T antigen (Northrup, *et al.*, *J. Biol. Chem.* [1993])). Each reporter plasmid contains a multimerized oligonucleotide of the

35 binding site for a distinct IL-2 enhancer-binding transcription factor within the context of the minimal IL-2 promoter or, alternatively, the intact IL-2 enhancer/promoter upstream of the reporter gene. After 24 hours, aliquots of

cells (approximately 10^5) were placed in microtiter wells containing log dilutions of bound anti-TAC (CD25) mAb (33B3.1; AMAC, Westbrook, ME). As a positive control and to control for transfection efficiency, ionomycin ($1 \mu\text{M}$) and PMA (25 ng/ml) were added to aliquots from each transfection. After an additional 14 hour incubation, the supernatants were assayed for the alkaline phosphatase activity and these activities were expressed relative to that of the positive control samples. The addition of 1 ng/ml FK506 dropped all activity due to NFAT to background levels, demonstrating that deactivations are in the same pathway as that blocked by FK506. Each data point obtained was the average of two samples and the experiment was performed several times with similar results. See Fig. 5. The data show that with a known extracellular receptor, one obtains an appropriate response with a reporter gene and different enhancers. Similar results were obtained when a MAb against the TcR complex (*i.e.* OKT3) was employed.

15

Example 2: Inhibitory Activity of the Immunosuppressant Drugs FK506 and Cyclosporin A (CsA) or the Dimeric Derivative Compounds FK1012A (8), FK1012B (5), and CsA dimer (PB-1-218).

Ionomycin ($1 \mu\text{M}$) and PMA (25 ng/ml) were added to 10^5 TAG-Jurkat cells. In addition, titrations of the various drugs were added. After 5 hours the cells were lysed in mild detergent (*i.e.* Triton X-100) and the extracts were incubated with the β -galactosidase substrate, MUG (methyl galactosidyl umbelliferone) for 1 hour. A glycine/EDTA stop buffer was added and the extracts assayed for fluorescence. Each data point obtained was the average of two samples and the experiment was performed several times with similar results. Curiously, FK1012B appears to augment mitogen activity slightly at the highest concentration (*i.e.* $5 \mu\text{g/ml}$); however, a control experiment shows that FK1012B is not stimulatory by itself. See Fig. 6.

Example 3. Activity of the Dimeric FK506 Derivative, FK1012A, on the Chimeric FKBP12/CD3 (1FK3) Receptor.

$5 \mu\text{g}$ of the eukaryotic expression vector, pBJ5, (based on pCDL-SR with a polylinker inserted between the 16S splice site and the poly A site), containing the chimeric receptor (1FK3), was co-transfected with $4 \mu\text{g}$ of the NFAT-inducible secreted alkaline phosphatase reporter plasmid, NFAT-SX. As a control, $5 \mu\text{g}$ of pBJ5 was used, instead of 1FK3/pBJ5, in a parallel transfection. After 24 hours, aliquots of each transfection containing approximately 10^5 cells

were incubated with log dilutions of the drug, FK1012A, as indicated. As a positive control and to control for transfection efficiency, ionomycin (1 μ m) and PMA (25 ng/ml) were added to aliquots from each transfection. After an additional 14 hour incubation, the supernatants were assayed for alkaline phosphatase activity and these activities were expressed relative to that of the positive control samples. The addition of 2 ng/ml FK506 dropped all stimulations to background levels, demonstrating that the activations are in the same pathway as that blocked by FK506. Hence, FK506 or cyclosporin will serve as effective antidotes to the use of these compounds. Each data point obtained was the average of two samples and the experiment was performed several times with similar results. See Fig. 7.

Example 4A. Activity of the Dimeric FK506 Derivative, FK1012B, on the Myristoylated Chimeric CD3 /FKBP12 (MZF3E) Receptor.

We have successfully demonstrated a number of approaches to ligand design and syntheses, including positive results with FK506-based HOD reagents named "FK1012"s. We have found that FK1012s achieve high affinity, 2:1 binding stoichiometry ($K_d(1) = 0.1$ nM; $K_d(2) = 0.8$ nM) and do not inhibit calcineurin-mediated TCR signaling. The ligands are neither "immunosuppressive" nor toxic (up to 0.1 mM in cell culture). Similarly, we have prepared a cyclosporin A-based homodimerizing agent, "(CsA)2" which binds to the CsA receptor, cyclophylin, with 1:2 stoichiometry, but which does not bind to calcineurin. Thus, like FK1012s, (CsA)2 does not inhibit signalling pathways and is thus neither immunosuppressive nor toxic.

These and other of our examples of ligand-mediated protein association resulted in the control of a signal transduction pathway. In an illustrative case, this was accomplished by creating an intracellular receptor comprised of a small fragment of Src sufficient for posttranslational myristoylation (M), the cytoplasmic tail of zeta (Z; a component of the B cell receptor was also used), three consecutive FKBP12s (F3) and a flu epitope tag (E). Upon expressing the construct MZF3E (Figure 18) in human (Jurkat) T cells, we confirmed that the encoded chimeric protein underwent FK1012-mediated oligomerization. The attendant aggregation of the zeta chains led to signaling via the endogenous TCR-signaling pathway (Figure 15), as evidenced by secretion of alkaline phosphatase (SEAP) in response to an FK1012 ($EC_{50} = 50$ nM). The promoter of the SEAP reporter gene was constructed to be transcriptionally activated by nuclear factor of activated T cells (NFAT), which is assembled in the nucleus

following TCR-signaling. FK1012-induced signaling can be terminated by a deaggregation process induced by a nontoxic, monomeric version of the ligand called FK506-M.

Specifically, 5 µg of the eukaryotic expression vector, pBJ5, containing a myristoylated chimeric receptor was co-transfected with 4 µg NFAT-SX. MZE, 5 MZF1E, MZF2E and MZF3E contain 0, 1, 2, or 3 copies of FKBP12, respectively, downstream of a myristoylated CD3 cytoplasmic domain (see Fig. 2). As a control, 5 µg of pBJ5 was used in a parallel transfection. After 24 hours, aliquots of each transfection containing approximately 10⁵ cells were 10 incubated with log dilutions of the drug, FK1012B, as indicated. As a positive control and to control for transfection efficiency, ionomycin (1 µm) and PMA (25 ng/ml) were added to aliquots from each transfection. After an additional 12 hour incubation, the supernatants were assayed for alkaline phosphatase activity and these activities were expressed relative to that of the positive 15 control samples. The addition of 1 ng/ml FK506 dropped all stimulations to near background levels, demonstrating that the activations are in the same pathway as that blocked by FK506. This result is further evidence of the reversibility of the subject cell activation. Each data point obtained was the average of two samples and the experiment was performed several times with 20 similar results. See Fig. 8. The myristoylated derivatives respond to lower concentrations of the ligand by about an order of magnitude and activate NF-AT dependent transcription to comparable levels, but it should be noted that the ligands are different. Compare Figs. 7 and 8.

In vivo FK1012-induced protein dimerization We next wanted to 25 confirm that intracellular aggregation of the MZF3E receptor is indeed induced by the FK1012. The influenza haemagglutinin epitope-tag (flu) of the MZF3E-construct was therefore exchanged with a different epitope-tag (flag-M2). The closely related chimeras, MZF3E_{flu} and MZF3E_{flag}, were coexpressed in Jurkat T cells. Immunoprecipitation experiments using anti-Flag-antibodies coupled to 30 agarose beads were performed after the cells were treated with FK1012A. In the presence of FK1012A (1µM) the protein chimera MZF3E_{flag} interacts with MZF3E_{flu} and is coimmunoprecipitated with MZF3E_{flag}. In absence of FK1012A, no coimmunoprecipitation of MZF3E_{flu} is observed. Related experiments with FKBP monomer constructs MZF1E_{flu} and MZF1E_{flag}, which 35 do not signal, revealed that they are also dimerized by FK1012A (Figure 19A). This reflects the requirement for aggregation observed with both the endogenous T cell receptor and our artificial receptor MZF3E.

FK1012-induced protein-tyrosine phosphorylation The intracellular domains of the TCR, CD3 and zeta-chains interact with cytoplasmic protein tyrosine kinases following antigen stimulation. Specific members of the Src family (lck and/or fyn) phosphorylate one or more tyrosine residues of activation motifs within these intracellular domains (tyrosine activation motif, TAM). The tyrosine kinase ZAP-70 is recruited (via its two SH2 domains) to the tyrosine phosphorylated T-cell-receptor, activated, and is likely to be involved in the further downstream activation of phospholipase C. β Addition of either anti-CD3 MAb or FK1012A to Jurkat cells stably transfected with MZF3E resulted in the recruitment of kinase activity to the zeta-chain as measured by an in vitro kinase assay following immunoprecipitation of the endogenous T cell receptor zeta chain and the MZF3E-construct, respectively. Tyrosine phosphorylation after treatment of cells with either anti-CD3 MAb or FK1012 was detected using monoclonal alpha-phosphotyrosine antibodies. Whole cell lysates were analysed at varying times after stimulation. A similar pattern of tyrosine-phosphorylated proteins was observed after stimulation with either anti-CD3 MAb or FK1012. The pattern consisted of a major band of 70 kDa, probably ZAP-70, and minor bands of 120 kDa, 62 kDa, 55 kDa and 42 kDa.

20

Example 4(B): Regulation of Programmed Cell Death with Immunophilin-Fas Antigen Chimeras

The Fas antigen is a member of the nerve growth factor (NGF)/tumor necrosis factor (TNF) receptor superfamily of cell surface receptors. Crosslinking of the Fas antigen with antibodies to its extracellular domain activates a poorly understood signaling pathway that results in programmed cell death or apoptosis. The Fas antigen and its associated apoptotic signaling pathway are present in most cells including possibly all tumor cells. The pathway leads to a rapid and unique cell death (2 h) that is characterized by condensed cytoplasm, the absence of an inflammatory response and fragmentation of nucleosomal DNA, none of which are seen in necrotic cell death.

We have also developed a second, inducible signaling system that leads to apoptotic cell death. Like the MZF3E pathway, this one is initiated by activating an artificial receptor that is the product of a constitutively expressed "responder" gene. However, the new pathway differs from the first in that our HOD reagents induce the synthesis of products of an endogenous pathway

rather than of the product of a transfected, inducible (e.g., reporter) gene.

Gaining control over the Fas pathway could have important implications for biological research and medicine in the future. Transgenic animals might be created with "death" responder genes under the control of cell-specific
5 promoters. Target cells could then be chemically ablated in the adult animal by treating it with a HOD reagent. In this way, the role of specific brain cells in memory or cognition or immune cells in the induction and maintenance of autoimmune disorders could be assessed. Death responder genes might be introduced into tumors using the human gene therapy technique developed by
10 M. Blaese and co-workers (Culver et al, *Science* 256 5063 (1992): 1550-2) and then subsequently activated by treating the patient with a HOD reagent (in analogy to the "gancyclovir" gene therapy clinical trials recently reported for the treatment of brain tumors). Finally, we contemplate a component of gene therapy in the future that would involve the coadministration of a death-
15 responder gene together with the therapeutic gene. This would provide a "failsafe" component to gene therapy. If something were to go awry (a commonly discussed concern is an integration-induced loss of a tumor suppressor gene leading to cancer), the gene therapy patient could take a "failsafe" pill that would kill all transfected cells. This concept caused us to
20 focus on the development of an orthogonal system of HOD reagents. Thus, we desired a second set of reagents that have no possibility of cross-reacting with the first, which would be used to turn on or off the transcription of therapeutic genes.

A chimeric cDNA has been constructed consisting of three FKBP12
25 domains fused to the cytoplasmic signaling domain of the Fas antigen (Figure 20). This construct, when expressed in human Jurkat and murine D10 T cells, can be induced to dimerize by an FK1012 reagent and initiate a signaling cascade resulting in FK1012-dependent apoptosis. The LD50 for FK1012A-mediated death of cells transiently transfected with MFF3E is 15 nM as
30 determined by a loss of reporter gene activity (Figure 20; for a discussion of the assay, see legend to Figure 21). These data coincide with measurements of cell death in stably transfected cell lines. Since the stable transfectants represent a homogeneous population of cells, they have been used to ascertain that death is due to apoptosis rather than necrosis (membrane blebbing, nucleosomal DNA
35 fragmentation). However, the transient transfection protocol requires much less work and has therefore been used as an initial assay system, as described below.

Example 4(C): Regulation of Programmed Cell Death with Cyclophilin-Fas Antigen Chimeras

We have also prepared a series of cyclophilin C-Fas antigen constructs and assayed their ability to induce (CsA)²-dependent apoptosis in transient expression assays (Figure 21A). In addition, (CsA)²-dependent apoptosis has been demonstrated with human Jurkat T cells stably transfected with the most active construct in the series, MC3FE (M = myristoylation domain of Src, C = cyclophilin domain, F = cytoplasmic tail of Fas, E = flu epitope tag). The cytoplasmic tail of Fas was fused either before or after 1, 2, 3, or 4 consecutive cyclophilin domains. Two control constructs were also prepared that lack the Fas domain. In this case we observed that the signaling domain functions only when placed after the dimerization domains. (The zeta chain constructs signal when placed either before or after the dimerization domains.) Both the expression levels of the eight signaling constructs, as ascertained by Western blotting, and their activities differed quantitatively (Figure 21B). The optimal system has thus far proved to be MC3FE. The LD₅₀ for (CsA)²-mediated cell death with MC3FE is ~200 nM. These data demonstrate the utility of the cyclophilin-cyclosporin interactions for regulating intracellular protein association and illustrate an orthogonal reagent system that will not cross-react with the FKBP12-FK1012 system. Further, in this case, the data show that only dimerization and not aggregation is required for initiation of signal transduction by the Fas cytoplasmic tail.

Mutation of the N-terminal glycine of the myristoylation signal to an alanine prevents myristoylation and hence membrane localization. We have also observed that the mutated construct (Δ MFF3E) was equally potent as an inducer of FK1012-dependent apoptosis, indicating that membrane localization is not necessary for Fas-mediated cell death.

Example 5. Construction of Murine Signalling Chimeric Protein.

The various fragments were obtained by using primers described in Fig. 4. In referring to primer numbers, reference should be made to Fig. 4.

An approximately 1.2 kb cDNA fragment comprising the I-E chain of the murine class II MHC receptor (*Cell*, 32, 745) was used as a source of the signal peptide, employing P#6048 and P#6049 to give a 70 bp *SacII-XhoI* fragment using PCR as described by the supplier (Promega). A second fragment was obtained using a plasmid comprising Tac (IL2 receptor chain) joined to the

transmembrane and cytoplasmic domains of CD3 (*PNAS*, 88, 8905). Using P#6050 and P#6051, a 320 bp *XhoI-EcoRI* fragment was obtained by PCR comprising the transmembrane and cytoplasmic domains of CD3. These two fragments were ligated and inserted into a *SacII-EcoRI* digested pBluescript (Stratagene) to provide plasmid, SPZ/KS.

To obtain the binding domain for FK506, plasmid rhFKBP (provided by S. Schreiber, *Nature* (1990) 346, 674) was used with P#6052 and P#6053 to obtain a 340 bp *XhoI-SalI* fragment containing human FKBP12. This fragment was inserted into pBluescript digested with *XhoI* and *SalI* to provide plasmid FK12/KS, which was the source for the FKBP12 binding domain. SPZ/KS was digested with *XhoI*, phosphatased (cell intestinal alkaline phosphatase; CIP) to prevent self-annealing, and combined with a 10-fold molar excess of the *XhoI-SalI* FKBP12-containing fragment from FK12/KS. Clones were isolated that contained monomers, dimers, and trimers of FKBP12 in the correct orientation. The clones 1FK1/KS, 1FK2/KS, and 1FK3/KS are comprised of in the direction of transcription; the signal peptide from the murine MHC class II gene I-E, a monomer, dimer or trimer, respectively, of human FKBP12, and the transmembrane and cytoplasmic portions of CD3. Lastly, the *SacII-EcoRI* fragments were excised from pBluescript using restriction enzymes and ligated into the polylinker of pBJ5 digested with *SacII* and *EcoRI* to create plasmids 1FK1/pBJ5, 1FK2/pBJ5, and 1FK3/pBJ5, respectively. See Figs. 3 and 4.

Example 6

25 A. Construction of Intracellular Signaling Chimera.

A myristoylation sequence from c-src was obtained from Pellman, *et al.*, *Nature* 314, 374, and joined to a complementary sequence of CD3 to provide a primer which was complementary to a sequence 3' of the transmembrane domain, namely P#8908. This primer has a *SacII* site adjacent to the 5' terminus and a *XhoI* sequence adjacent to the 3' terminus of the myristoylation sequence. The other primer P#8462 has a *SalI* recognition site 3' of the sequence complementary to the 3' terminus of CD3, a stop codon and an *EcoRI* recognition site. Using PCR, a 450 bp *SacII-EcoRI* fragment was obtained, which was comprised of the myristoylation sequence and the CD3 sequence fused in the 5' to 3' direction. This fragment was ligated into *SacII/EcoRI*-digested pBJ5(*XhoI*)(*SalI*) and cloned, resulting in plasmid MZ/pBJ5. Lastly, MZ/pBJ5 was digested with *SalI*, phosphatased, and combined with a 10-fold molar

excess of the *XhoI-SalI* FKBP12-containing fragment from FK12/KS and ligated. After cloning, the plasmids comprising the desired constructs having the myristoylation sequence, CD3 and FKBP12 multimers in the 5'-3' direction were isolated and verified as having the correct structure. See Figs. 2 and 4.

5

B. Construction of expression cassettes for intracellular signaling chimeras

The construct MZ/pBJ5 (MZE/pBJ5) is digested with restriction enzymes *XhoI* and *SalI*, the TCR ζ fragment is removed and the resulting vector is ligated with a 10 fold excess of a monomer, dimer, trimer or higher order multimer of FKBP12 to make MF1E, MF2E, MF3E or MF_nE/pBJ5. Active domains designed to contain compatible flanking restriction sites (i.e. *XhoI* and *SalI*) can then be cloned into the unique *XhoI* or *SalI* restriction sites of MF_nE/pBJ5.

15 Example 7. Construction of Nuclear Chimera

A. GAL4 DNA binding domain - FKBP domain(s) - epitope tag. The GAL4 DNA binding domain (amino acids 1-147) was amplified by PCR using a 5' primer (#37) that contains a *SacII* site upstream of a Kozak sequence and a translational start site, and a 3' primer (#38) that contains a *SalI* site. The PCR product was isolated, digested with *SacII* and *SalI*, and ligated into pBluescript II KS (+) at the *SacII* and *SalI* Sites, generating the construct pBS-GAL4. The construct was verified by sequencing. The *SacII/SalI* fragment from pBS-GAL4 was isolated and ligated into the IFK1/pBJ5 and IFK3/pBJ5 constructs (containing the myristoylation sequence, see Example 6) at the *SacII* and *XhoI* sites, generating constructs GF1E, GF2E and GF3E.

B. HNF1 dimerization/DNA binding domain - FKBP domain(s) - tag.
 The HNF1a dimerization/DNA binding domain (amino acids 1-282) was amplified by PCR using a 5' primer (#39) that contains a *SacII* site upstream of a Kozak sequence and a translational start site, and a 3' primer (#40) that contains a *Sall* site. The PCR product was isolated, digested with *SacII* and *Sall*, and ligated into pBluescript II KS (+) at the *SacII* and *Sall* sites, generating the construct pBS-HNF. The construct was verified by sequencing. The *SacII*/*Sall* fragment from pBS-HNF was isolated and ligated into the IFK1/pBJ5 and IFK3/pBJ5 constructs at the *SacII* and *XhoI* sites, generating constructs HF1E, HF2E and HF3E.

C. FKBP domain(s)-VP16 transcrip. activation domain(s)-epitope tag.

These constructs were made in three steps: (i) a construct was created from IFK3/pBJ5 in which the myristoylation sequence was replaced by a start site immediately upstream of an *XhoI* site, generating construct SF3E; (ii) a nuclear localization sequence was inserted into the *XhoI* site, generating construct NF3E; (iii) the VP16 activation domain was cloned into the *Sall* site of NF3E, generating construct NF3V1E.

- (i). Complementary oligonucleotides (#45 and #46) encoding a Kozak sequence and start site flanked by *SacII* and *XhoI* sites were annealed, phosphorylated and ligated into the *SacII* and *XhoI* site of MF3E, generating construct SF3E.

Insertion of generic start site

15

- (ii). Complementary oligonucleotides (#47 and #48) encoding the SV40 T antigen nuclear localization sequence flanked by a 5' *Sall* site and a 3' *XhoI* site were annealed, phosphorylated and ligated into the *XhoI* site of SF1E, generating the construct NF1E. The construct was verified by DNA sequencing. A construct containing the mutant or defective form of the nuclear localization sequence, in which a threonine is substituted for the lysine at position 128, was also isolated. This is designated NF1E-M. Multimers of the FKBP12 domain were obtained by isolating the FKBP12 sequence as an *XhoI/Sall* fragment from pBS-FKBP12 and ligating this fragment into NF1E linearized with *XhoI*. This resulted in the generation of the constructs NF2E and NF3E.

35

Insertion of NLS into generic start site

Threonine at position 128 results in a defective NLS.

- 10 (iii). The VP16 transcriptional activation domain (amino acids 413-490) was amplified by PCR using a 5' primer (#43) that contains *Sall* site and a 3' primer (#44) that contains an *XhoI* site. The PCR product was isolated, digested with *Sall* and *XhoI*, and ligated into MF3E at the *XhoI* and *Sall* sites, generating the construct MV1E. The construct was verified by sequencing.
- 15 Multimerized VP16 domains were created by isolating the single VP16 sequence as a *XhoI/Sall* fragment from MV1E and ligating this fragment into MV1E linearized with *XhoI*. Constructs MV2E, MV3E and MV4E were generated in this manner. DNA fragments encoding one or more multiple VP16 domains were isolated as *XhoI/Sall* fragments from MV1E or MV2E and ligated into
- 20 NF1E linearized with *Sall*, generating the constructs NF1V1E and NF1V3E. Multimers of the FKBP12 domain were obtained by isolating the FKBP12 sequence as an *XhoI/Sall* fragment from pBS-FKBP12 and ligating this fragment into NF1V1E linearized with *XhoI*. This resulted in the generation of the constructs NF2V1E and NF3V1E.

Example 8. Demonstration of Transcriptional Induction.

- Jurkat TAg cells were transfected with the indicated constructs (5 µg of each construct) by electroporation (960 µF, 250-v). After 24 hours, the cells
 20 were resuspended in fresh media and aliquoted. Half of each transfection was incubated with the dimeric FK506 derivative, (Example 14) at a final concentration of 1 µM. After 12 hours, the cells were washed and cellular extracts were prepared by repeated freeze-thaw. Chloramphenicol acetyltransferase (CAT) activity was measured by standard protocols.
 25 Molecular Cloning: A Laboratory Manual, Sambrook et al. eds. (1989) CSH Laboratory, pp. 16-59 ff. The data (Fig. 22) demonstrates CAT activity present in 70 µL of extract (total extract volume was 120 µL) after incubation at 37°C for 18 hours. The samples employed in the assays are as follows:

1. G5E4TCAT (GAL4-CAT reporter plasmid)
- 30 2. G5E4TCAT, GAL4-VP16
3. G5E4TCAT, NF3V1E
4. G5E4TCAT, GF2E
5. G5E4TCAT, GF2E, NF3V1E
6. G5E4TCAT, GF3E, NF3V1E

35

Synthetic Chemistry Examples

As indicated elsewhere, compounds of particular interest at present as oligomerization agents have the following structure:

5

wherein "linker" is a linker moiety such as described herein which is covalently linked to "n" (an integer from 2 to about 5, usually 2 or 3) receptor binding moieties ("rbm"s) which may be the same or different. As discussed elsewhere herein, the receptor binding moiety is a ligand (or analog thereof) for a known receptor, such as are enumerated in Section V(C), and including FK506, FK520, rapamycin and analogs thereof which are capable of binding to an FKBP; as well as cyclosporins, tetracyclines, other antibiotics and macrolides and steroids which are capable of binding to respective receptors.

15

The linker is a bi- or multi-functional molecule capable of being covalently linked ("—") to two or more receptor binding moieties. Illustrative linker moieties are disclosed in Section VI(A) and in the various Examples and include among others C2-C20 alkylene, C4-C18 azalkylene, C6-C24 N-alkylene azalkylene, C6-C18 arylene, C8-C24 aralkylene and C8-C36 bis-carboxamido alkylene.

20

These compounds may be prepared using commercially available materials and/or procedures known in the art. Engineered receptors for these compounds may be obtained as described infra. Compounds of particular interest are those which bind to a receptor with a K_d of less than 10^{-6} , preferably less than about 10^{-7} and even more preferably, less than 10^{-8} .

25

One subclass of oligomerizing agents of interest are those in which one or more of the receptor binding moieties is FK506, an FK-506-type compound or a derivative thereof, wherein the receptor binding moieties are covalently attached to the linker moiety through the allyl group at C21 (using FK506 numbering) as per compound 5 or 13 in Fig 23A, or through the cyclohexyl ring (C29-C34), e.g. through the C32 hydroxyl as per compounds 8, 16, 17 in Fig 23B. Compounds of this class may be prepared by adaptation of methods disclosed herein, including in the examples which follow.

30

Another subclass of oligomerizing agents of interest are those in which at least one of the receptor binding moieties is FK520 or a derivative thereof, wherein the molecules of FK520 or derivatives thereof are covalently attached to

35

the linker moiety as in FK1040A or FK 1040B in Fig 10. Compounds of this class may be prepared by adaptation of Scheme 1 in Fig. 10, Scheme 2 in Figs. 11A and 11B or Scheme 3 in Fig 12 and Fig 13.

A further subclass of oligomerizing agents of interest are those in which
5 at least one of the receptor binding moieties is cyclosporin A or a derivative.

It should be appreciated that these and other oligomerizing agents of this invention may be homo-oligomerizing reagents (where the rbm's are the same) or hetero-oligomerizing agents (where the rbm's are different). Hetero-oligomerizing agents may be prepared by analogy to the procedures presented herein, including
10 Scheme 3 in Figure 13 and as discussed elsewhere herein.

The following synthetic examples are intended to be illustrative.

A. General Procedures. All reactions were performed in oven-dried glassware under a positive pressure of nitrogen or argon. Air and moisture
15 sensitive compounds were introduced via syringe or cannula through a rubber septum.

B. Physical Data. Proton magnetic resonance spectra (¹H NMR) were recorded on Bruker AM-500 (500 MHz), and AM-400 (400 MHz) spectrometers. Chemical shifts are reported in ppm from tetramethylsilane
20 using the solvent resonance as an internal standard (chloroform, 7.27 ppm). Data are reported as follows: chemical shift, multiplicity (s = singlet, d = doublet, t = triplet, q = quartet, br = broadened, m = multiplet), coupling constants (Hz), integration. Low and high-resolution mass spectra were obtained.

C. Chromatography. Reactions were monitored by thin layer chromatography (TLC) using E. Merck silica gel 60F glass plates (0.25 mm). Components were visualized by illumination with long wave ultraviolet light, exposed to iodine vapor, and/or by dipping in an aqueous ceric ammonium molybdate solution followed by heating. Solvents for chromatography were
30 HPLC grade. Liquid chromatography was performed using forced flow (flash chromatography) of the indicated solvent system on E. Merck silica gel 60 (230-400 mesh).

D. Solvents and Reagents. All reagents and solvents were analytical grade and were used as received with the following exceptions.
35 Tetrahydrofuran (THF), benzene, toluene, and diethyl ether were distilled from sodium metal benzophenone ketyl. Triethylamine and acetonitrile were distilled from calcium hydride. Dichloromethane was distilled from phosphorous

pentoxide. Dimethylformamide (DMF) was distilled from calcium hydride at reduced pressure and stored over 4 Å molecular sieves.

Preparation of FK506 Derivatives

5

Example 9. Hydroboration/Oxidation of FK506-TBS₂ (1 to 2).

The hydroboration was performed according to the procedure of Evans (Evans, *et al.*, *JACS* (1992) 114, 6679; *ibid.* (1992) 6679-6685). (See Harding, *et al.*, *Nature* (1989) 341, 758 for numbering.) A 10-mL flask was charged with
10 24,32-bis[(*tert*-butyldimethylsilyl)oxy]-FK506 (33.8 mg, 0.033 mmol) and [Rh(nbd)(diphos-4)]BF₄ (3.1 mg, 0.004 mmol, 13 mol %). The orange mixture was dissolved in toluene (2.0 mL) and the solvent was removed under reduced pressure over four hours. The flask was carefully purged with nitrogen and the orangish oil was dissolved in THF (3.0 mL, 10 mM final concentration) and
15 cooled to 0°C with an ice water bath. Catecholborane (98 µL, 0.098 mmol, 1.0 M solution in THF, 3.0 equiv.) was added via syringe and the resulting solution was stirred at 0°C for 45 min. The reaction was quenched at 0°C with 0.2 mL of THF/EtOH (1:1) followed by 0.2 mL of pH 7.0 buffer (Fisher; 0.05 M phosphate) then 0.2 mL of 30% H₂O₂. The solution was stirred at room
20 temperature for at least 12 h. The solvent was removed under reduced pressure and the remaining oil was dissolved in benzene (10 mL) and washed with saturated aqueous sodium bicarbonate solution (10 mL). The phases were separated and the aqueous phase was back-extracted with benzene (2 x 10 mL). The organic phases were combined and washed once with saturated
25 aqueous sodium bicarbonate solution (10 mL). The benzene phase was dried with MgSO₄, concentrated, and subjected to flash chromatography (2:1 hexane:ethyl acetate) providing the desired primary alcohol as a clear, colorless oil (12.8 mg, 0.012 mmol, 37%).

Preparation of Mixed Carbonate (2 to 3). The preparation of the mixed
30 carbonate was accomplished by the method of Ghosh (Ghosh, *et al.*, *Tetrahedron Lett.* (1992) 33, 2781-2784). A 10-mL flask was charged with the primary alcohol (29.2 mg, 0.0278 mmol) and benzene (4 mL). The solvent was removed under reduced pressure over 60 min. The oil was dissolved in acetonitrile (2.0 mL, 14 mM final concentration) and stirred at 20°C as triethylamine (77 µL,
35 0.56 mmol) was added. N,N'-disuccinimidyl carbonate (36 mg, 0.14 mmol) was added in one portion and the solution was stirred at 20°C for 46 h. The reaction mixture was diluted with dichloromethane and washed with saturated

aqueous sodium bicarbonate solution (10 mL). The phases were separated and the aqueous layer was back-extracted with dichloromethane (2 x 10 mL). The organic phases were combined and dried (MgSO₄), concentrated, and subjected to flash chromatography (3:1 to 2:1 to 1:1 hexane:ethyl acetate). The desired
5 mixed carbonate was isolated as a clear, colorless oil (16.8 mg, 0.014 mmol, 51%).

Dimerization of FK506 (3 to 4). A dry, 1-mL conical glass vial (Kontes Scientific Glassware) was charged with the mixed carbonate (7.3 mg, 0.0061 mmol) and acetonitrile (250 μ L, 25 mM final concentration).
10 Triethylamine (10 μ L, 0.075 mmol) was added followed by *p*-xylylenediamine (8.3 μ L, 0.0027 mmol, 0.32 M solution in DMF). The reaction stirred 22 h at 20°C and was quenched by dilution with dichloromethane (10 mL). The solution was washed with saturated aqueous sodium bicarbonate solution
15 with dichloromethane (2 x 10 mL). The organic phases were combined and dried (MgSO₄), concentrated, and subjected to flash chromatography (3:1 to 2:1 to 1:1 hexane:ethyl acetate) providing the desired protected dimer as a clear, colorless oil (4.3 mg, 1.9 μ mol, 70%).

Deprotection of the FK506 Dimer (4 to 5). The protected dimer (3.3 mg, 1.4 μ mol) was placed in a 1.5-mL polypropylene tube fitted with a spin vane. Acetonitrile (0.5 mL, 3 mM final concentration) was added and the solution stirred at 20°C as HF (55 μ L, 48% aqueous solution; Fisher) was added. The solution was stirred 18 h at room temperature. The deprotected FK506 derivative was then partitioned between dichloromethane and saturated
25 aqueous sodium bicarbonate in a 15-mL test tube. The tube was vortexed extensively to mix the phases and, after separation, the organic phase was removed with a pipet. The aqueous phase was back-extracted with dichloromethane (4 x 2 mL), and the combined organic phases were dried (MgSO₄), concentrated and subjected to flash chromatography (1:1:1 hexane:THF:ether to
30 1:1 THF:ether) providing the desired dimer as a clear, colorless oil (1.7 mg, 0.93 μ mol, 65%).

Following the above procedure, other monoamines and diamines may be used, such as benzylamine (14) octamethylenediamine, decamethylenediamine, etc.

35

Example 10. Reduction of FK506 with L-Selectride (FK506 to 6).

Danishefsky and coworkers have shown that the treatment of FK506 with L-

Selectride provides 22-dihydro-FK506 with a boronate ester engaging the C24 and C22 hydroxyl groups (Coleman and Danishefsky, *Heterocycles* (1989) 28, 157-161; Fisher, *et al.*, *J. Org. Chem.* (1991) 56, 2900-2907).

Preparation of the Mixed Carbonate (6 to 7). A 10-mL flask was
5 charged with 22-dihydro-FK506-*sec*-butylboronate (125.3 mg, 0.144 mmol) and acetonitrile (3.0 mL, 50 mM final concentration) and stirred at room temperature as triethylamine (200 μ L, 1.44 mmol, 10 equiv.) was added to the clear solution. N,N'-disuccinimidyl carbonate (184.0 mg, 0.719 mmol) was added in one portion, and the clear solution was stirred at room temperature for
10 44 h. The solution was diluted with ethyl acetate (20 mL) and washed with saturated aqueous sodium bicarbonate (10 mL) and the phases were separated. The aqueous phase was then back-extracted with ethyl acetate (2 x 10 mL), and the organic phases were combined, dried (MgSO₄), and the resulting oil was subjected to flash chromatography (1:1 to 1:2 hexane:ethyl acetate) providing
15 the desired mixed carbonate as a clear, colorless oil (89.0 mg, 0.088 mmol, 61%).

Dimerization of FK506 Mixed Carbonate (7 to 8). A dry, 1-mL conical glass vial (Kontes Scientific Glassware) was charged with the mixed carbonate (15.0 mg, 0.0148 mmol) and dichloromethane (500 μ L, 30 mM final concentration). The solution was stirred at room temperature as triethylamine
20 (9 μ L, 0.067 mmol, 10 equiv.) was added followed by *p*-xylylenediamine (0.8 mg, 0.0059 mmol). The reaction stirred 16 h at 20°C and was quenched by dilution with dichloromethane (5 mL). The solution was washed with saturated aqueous sodium bicarbonate solution (5 mL). The phases were separated and the aqueous layer was back-extracted with dichloromethane (2 x 5 mL). The
25 organic phases were combined and dried (MgSO₄), concentration, and subjected to flash chromatography (1:1 to 1:2 hexane:ethyl acetate) providing the desired dimer as a clear, colorless oil (7.4 mg, 3.8 μ mol, 65%).

Following the above procedure, other, monoamines, diamines or triamines may be used in place of the xylylenediamine, such as benzylamine
30 (15), octylenediamine, decamethylenediamine (16), bis-*p*-dibenzylamine, N-methyl diethyleneamine, tris-aminoethylamine (17), tris-aminopropylamine, 1,3,5-triaminomethylcyclohexane, *etc.*

Example 11. Oxidative Cleavage and Reduction of FK506 (1 to 9). The
35 osmylation was performed according to the procedure of Kelly (VanRheenen, *et al.*, *Tetrahedron Lett.* (1976) 17, 1973-1976). The cleavage was performed according to the procedure of Danishefsky (Zell, *et al.*, *J. Org. Chem.* (1986) 51,

5032-5036). The aldehyde reduction was performed according to the procedure of Krishnamurthy (*J. Org. Chem.*, (1981) 46, 4628-4691). A 10 mL flask was charged with 24,32-bis[*tert*-butyldimethylsilyl]oxy]-FK506 (84.4 mg, 0.082 mmol), 4-methylmorpholine N-oxide (48 mg, 0.41 mmol, 5 equiv), and THF (2.0 mL, 41 mM final concentration). Osmium tetroxide (45 μ L, 0.008 mmol, 0.1 equiv) was added via syringe. The clear, colorless solution was stirred at room temperature for 5 hr. The reaction was then diluted with 50% aqueous methanol (1.0 mL) and sodium periodate (175 mg, 0.82 mmol, 10 equiv) was added in one portion. The cloudy mixture was stirred 40 min at room temperature, diluted with ether (10 mL), and washed with saturated aqueous sodium bicarbonate solution (5 mL). The phases were separated and the aqueous layer was back-extracted with ether (2 x 5 mL). The combined organic layers were dried (MgSO_4) and treated with solid sodium sulfite (50 mg). The organic phase was then filtered and concentrated and the oil was subjected to flash chromatography (3:1 to 2:1 hexane:ethyl acetate) providing the intermediate, unstable aldehyde (53.6 mg) as a clear, colorless oil. The aldehyde was immediately dissolved in THF (4.0 mL) and cooled to -78°C under an atmosphere of nitrogen, and treated with lithium tris[(3-ethyl-3-pentyl)oxy]aluminum hydride (0.60 mL, 0.082 mmol, 0.14 M solution in THF, 1.0 equiv). The clear solution was allowed to stir for 10 min at -78°C then quenched by dilution with ether (4 mL) and addition of saturated aqueous ammonium chloride (0.3 mL). The mixture was allowed to warm to room temperature and solid sodium sulfate was added to dry the solution. The mixture was then filtered and concentrated and the resulting oil was subjected to flash chromatography (2:1 hexane:ethyl acetate) giving the desired alcohol as a clear, colorless oil (39.5 mg, 0.038 mmol, 47%).

Preparation of Mixed Carbonate (9 to 10). The preparation of the mixed carbonate was accomplished by the method of Ghosh, *et al.*, *Tetrahedron Lett.* (1992) 33, 2781-2784). A 10 mL flask was charged with the primary alcohol (38.2 mg, 0.0369 mmol) and acetonitrile (2.0 mL, 10 mM final concentration) and stirred at room temperature as 2,6-lutidine (43 μ L, 0.37 mmol, 10 equiv) was added. *N,N'*-disuccinimidyl carbonate (48 mg, 0.18 mmol) was added in one portion and the solution was stirred at room temperature for 24 h. The reaction mixture was diluted with ether (10 mL) and washed with saturated aqueous sodium bicarbonate solution (10 mL). The phases were separated and the aqueous layer was back-extracted with ether (2 x 10 mL). The organic phases were combined and dried (MgSO_4), concentrated, and subjected to flash

chromatography (2:1 to 1:1 hexane:ethyl acetate). The desired mixed carbonate was isolated as a clear, colorless oil (32.6 mg, 0.028 mmol, 75%).

Preparation of Benzyl Carbamate (10 to 11). A dry, 1 mL conical glass vial (Kontes Scientific Glassware) was charged with the mixed carbonate 10 (8.7 mg, 0.0074 mmol) and acetonitrile (500 μ L, 15 mM final concentration). The solution was stirred at room temperature as triethylamine (10 μ L, 0.074 mmol, 10 equiv) was added followed by benzylamine (1.6 μ L, 0.015 mmol, 2 equiv). The reaction stirred 4 h at room temperature. The solvent was removed with a stream of dry nitrogen and the oil was directly subjected to flash chromatography (3:1 to 2:1 hexane:ethyl acetate) providing the desired protected monomer as a clear, colorless oil (6.2 mg, 5.3 μ mol, 72%).

The protected monomer (.2 mg, 5.3 μ mol) was placed in a 1.5 mL polypropylene tube fitted with a spin vane. Acetonitrile (0.5 mL, 11 mM final concentration) was added and the solution stirred at room temperature as HF (55 μ L, 48% aqueous solution; Fisher, 3.0 N final concentration) was added. The solution was stirred 18 h at room temperature. The deprotected FK506 derivative was then partitioned between dichloromethane and saturated aqueous sodium bicarbonate in a 15 mL test tube. The tube was vortexed extensively to mix the phases and, after separation, the organic phase was removed with a pipet. The aqueous phase was back-extracted with dichloromethane (4 x 2 mL), and the combined organic phases were dried (MgSO_4), concentrated and subjected to flash chromatography (1:1 to 0:1 hexane:ethyl acetate) providing for the desired deprotected benzylcarbamate as a clear, colorless oil (3.9 mg, 4.1 μ mol, 78%).

By replacing the benzylamine with a diamine such as xylylenediamine (12), hexamethylenediamine, octamethylenediamine, decamethylenediamine (13) or other diamines, dimeric compounds of the subject invention are prepared.

Example 12. Preparation of the Mixed Carbonate of FK506 (12). A 10-mL flask was charged with 24, 32-bis [(tert-butyl dimethylsilyl)oxy]-FK506 (339.5 mg, 0.329 mmol), 4-methylmorpholine N-oxide (193 mg, 1.64 mmol, 5 equiv), water (0.20 mL) and THF (8.0 mL, 41 mM final concentration). Osmium tetroxide (0.183 mL, 0.033 mmol, 0.1 equiv, 0.18 M soln in water) was added via syringe. The clear, colorless solution was stirred at room temperature for 4.5 h. The reaction was diluted with 50% aqueous methanol (4.0 mL) and sodium periodate (700 mg, 3.29 mmol, 10 equiv) was added in one portion. The cloudy mixture was stirred 25 min at room temperature, diluted with ether (20 mL), and

washed with saturated aqueous sodium bicarbonate solution (10 mL). The phases were separated and the aqueous layer was back-extracted with ether (2x10 mL). The combined organic layers were dried over MgSO₄ and solid sodium sulfite (50 mg). The organic phase was then filtered and concentrated and the resulting aldehyde was immediately dissolved in THF (8.0 mL) and cooled to -78 °C under an atmosphere of nitrogen, and treated with lithium tris [(3-ethyl-3-pentyl)oxy] aluminum hydride (2.35 mL, 0.329 mmol, 0.14 M solution of THF, 1.0 equiv). The clear solution was allowed to stir for 60 min at -78 °C (monitored closely by TLC) then quenched at -78 °C by dilution with ether (5 mL) and addition of saturated aqueous ammonium chloride (0.3 mL). The mixture was allowed to warm to room temperature and solid sodium sulfate was added to dry the solution. The mixture was stirred 20 min, filtered, concentrated, and the resulting oil was immediately dissolved in acetonitrile (10 mL). To the solution of the resulting primary alcohol in CH₃CN was added 2,6-lutidine (0.380 mL, 3.3. mmol, 10 equiv) and N,N'-disuccinimidyl carbonate (420 mg, 1.65 mmol, 5 equiv). The heterogenous mixture was stirred at room temperature for 19 h, at which time the solution was diluted with ether (30 mL) and washed with saturated aqueous sodium bicarbonate (20 mL). The aqueous phase was back-extracted with ether (2x10 mL). The organic phases were combined and dried (MgSO₄), concentrated, and subjected to flash chromatography (3:1 to 2:1 to 1:1 hexane/ethyl acetate). The desired mixed carbonate 12 was isolated as a clear, colorless oil (217 mg, 0.184 mmol, 56% overall for 4 steps)

Example 13. Preparation of 24, 24', 32, 32'-tetrakis [(tert-butyl)dimethylsilyl]oxy]-FK1012-A. (p-xylylenediamine bridge) A dry, 1-mL conical glass vial was charged with the mixed carbonate (23.9 mg, 0.0203 mmol) and acetonitrile (500 µL, 41 mM final concentration). Triethylamine (28 µL, 0.20 mmol, 10 equiv) was added followed by p-xylylenediamine (46 µL, 0.0101 mmol, 0.22 M solution in DMF). The reaction stirred 18 h at room temperature, the solvent was removed with a stream of dry nitrogen, and the oil was directly subjected to flash chromatography (3:1 to 2:1 to 1:1 hexane/ethyl acetate) affording the desired protected dimer as a clear, colorless oil (11.9 mg, 5.3 µmol, 52%)

35

Example 14. Preparation of FK1012-A (p-xylylenediamine bridge) (13). The protected dimer (11.0 mg, 4.9 µmol) was placed in a 1.5-mL polypropylene tube

fitted with a spin vane. Acetonitrile (0.50 mL, 10 mM final concentration) was added, and the solution stirred at 20 °C as HF (55 µL, 48% aqueous solution; Fisher, 3.0 N final concentration) was added. The solution was stirred 16h at room temperature. The deprotected FK506 derivative was then partitioned
5 between dichloromethane and saturated aqueous sodium bicarbonate in a 15-mL test tube. The tube was vortexed extensively to mix the phases and, after separation, the organic phase was removed with a pipet. The aqueous phase was back-extracted with dichloromethane (4x2 mL), and the combined organic phases were dried (MgSO₄), concentrated and subjected to flash
10 chromatography (1:1:1 hexane/THF/ether to 1:1 THF/ether) providing FK1012-A as a clear, colorless oil (5.5 mg, 3.0 µmol, 63%).

Example 15. Preparation of 24, 24', 32, 32'-tetrakis[(ter-butyl)dimethylsilyl]oxy]-FK1012-B (diaminodecane bridge). A dry, 1-mL
15 conical glass vial was charged with the mixed carbonate (53.3 mg, 0.0453 mmol) and acetonitrile (2.0 mL, 11 mM final concentration). Triethylamine (16 µL, 0.11 mmol, 5 equiv) was added followed by diaminodecane (61 µL, 0.0226 mmol, 0.37 M solution in DMF). The reaction stirred 12 h at room temperature, the solvent was removed with a stream of dry nitrogen, and the oil was directly
20 subjected to flash chromatography (3:1 to 2:1 to 1:1 hexane/ethyl acetate) affording the desired protected dimer as a clear, colorless oil (18.0 mg, 7.8 µmol, 35%).

Example 16. Preparation of FK1012-B (diaminodecane -1,10 bridge) (14).
25 The protected dimer (18.0 mg, 7.8 µmol) was placed in a 1.5-mL polypropylene tube fitted with a stirring flea. Acetonitrile (0.45 mL, 16 mM final concentration) was added, and the solution stirred at room temperature as HF (55 µL, 48% aqueous solution; Fisher, 3.6 N final concentration) was added. The solution was stirred 17 h at 23 °C. The product FK1012-B was then
30 partitioned between dichloromethane and saturated aqueous sodium bicarbonate in a 15-mL test tube. The tube was vortexed extensively to mix the phases and, after separation, the organic phase was removed with a pipet. The aqueous phase was back-extracted with dichloromethane (4x2 mL), and the combined organic phases were dried (MgSO₄), concentrated and subjected to
35 flash chromatography (100% ethyl acetate to 20:1 ethyl acetate/methanol) affording FK1012-B as a clear, colorless oil (5.3 mg, 2.9 µmol, 37%).

Example 17. Preparation of 24, 24', 32, 32'-tetrakis[(tert-butyl)dimethylsilyl]oxy]-FK1012-C (his-p-aminomethylbenzoyl diaminodecane bridge). A dry 25-mL tear-shaped flask was charged with the diamine linker (15.1 mg, 0.0344 mmol) and 1.0 mL of DMF. In a separate flask, the mixed carbonate and triethylamine (0.100 mL, 0.700 mmol, 20 equiv) were dissolved in 2.0 mL of dichloromethane then added slowly (4x0.50 mL) to the stirring solution of his-p-aminomethylbenzoyl, diaminodecane -1,10. The flask containing the mixed carbonate 12 was washed with dichloromethane (2x0.50 mL) to ensure complete transfer of the mixed carbonate 12. The reaction stirred 16 h at 23 °C, the solvent was removed with a stream of dry nitrogen, and the oil was directly subjected to flash chromatography (1:1 to 1:2 hexane/ethyl acetate) to afford the desired protected dimer as a clear, colorless oil (29.6 mg, 11.5 µmol, 34%).

Example 18. Preparation of FK1012-C (15). The protected dimer (29.6 mg, 11.5 µmol) (17) was placed in a 1.5-mL polypropylene tube fitted with a stirring flea. Acetonitrile (0.45 mL, 23 mM final concentration) was added, and the solution stirred at room temperature as HF (55 µL, 48% aqueous solution; Fisher, 3.6 N final concentration) was added. The solution was stirred 17 h at room temperature. The desired symmetrical dimer was then partitioned between dichloromethane and saturated aqueous sodium bicarbonate in a 15-mL test tube. The tube was vortexed extensively to mix the phases and, after separation, the organic phase was removed with a pipet. The aqueous phase was back-extracted with dichloromethane (4x2 mL), and the combined organic phases were dried (MgSO₄), concentrated and subjected to flash chromatography (100% ethyl acetate to 15:1 ethyl acetate/methanol) affording FK1012-C as a clear, colorless oil (11.5 mg, 5.5 µmol, 47%).

Preparation of CsA Derivatives

Example 19. MeBmt(OAc)-OH¹CsA (2). MeBmt(OAc)-OAc¹-CsA (1) (161 mg, 124 µmol) (see Eberle and Nuninger, *J. Org. Chem.* (1992) 57, 2689) was dissolved in Methanol (10 mL). KOH (196 mg) was dissolved in water (8 mL). 297 mL of the KOH solution (.130 mmol, 1.05 eq.) was added to the solution of (1) in MeOH. This new solution was stirred at room temperature under an inert atmosphere for 4 hours at which time the reaction was quenched with acetic acid (2 mL). The reaction mixture was purified by reversed phase

HPLC using a 5 cm x 25 cm, 12 μ , 100 A, C18 column at 70°C eluting with 70% acetonitrile/H₂O containing 0.1% (v/v) Trifluoroacetic acid to give 112 mg (72%) of the desired monoacetate (2).

MeBmt(OAc)-OCOIm¹CsA (3). MeBmt(OAc)-OH¹-CsA (2) (57 mg, 45.5 μ mol) and carbonyldiimidazole (15 mg, 2 eq., 91 μ mol.) were transferred into a 50 mL round bottom flask and dissolved in dry THF (6 mL). Diisopropylethylamine (32 μ L, 4 eq., 182 μ mol) was added and then the solvent was removed on a rotary evaporator at room temperature. The residue was purified by flash chromatography on silica gel using ethyl acetate as eluent to give 45 mg (73%) of the desired carbamate (3).

Tris-(2-aminoethyl)amine CsA Trimer Triacetate (6). MeBmt(OAc)-OCOIm¹-CsA (3) (7.5 mg, 5.54 μ mol, 3.1 eq.) was dissolved in THF (100 μ L). Diisopropylethylamine (62 μ L, 5 eq., 8.93 μ mol of a solution containing 100 μ L of amine in 4 mL THF) was added followed by tris(2-aminoethyl)amine (26 μ L, 1.79 μ mol, 1 eq. of a solution containing 101 mg of tris-amine in 10 mL THF). This solution was allowed to stir under N₂ atmosphere for 5 days. The reaction mix was evaporated and then purified by flash chromatography on silica gel using 0-5% methanol in chloroform to give 4.1 mg of desired product (6).

Example 20. Diaminodecane CsA Dimer (8). Solid Na metal (200 mg, excess) was reacted with dry methanol (10 mL) at 0°C. Diaminodecane CsA Dimer Diacetate (5) (4.0 mg) was dissolved in MeOH (5 mL). 2.5 mL of the NaOMe solution was added to the solution of (5). After 2.5 hours of stirring at room temperature under an inert atmosphere, the solution was quenched with acetic acid (2 mL) and the product was purified by reversed phase HPLC using a 5 mm x 25 mm, 12 μ , 100 A, C18 column at 70°C eluting with 70-95% acetonitrile/H₂O over 20 minutes containing 0.1% (v/v) Trifluoroacetic acid to give 2.5 mg (60%) of the desired diol.

The diaminodecane CsA Dimer Diacetate (5) was prepared by replacing the tris(2-aminoethyl)amine with 0.45 eq. of 1,10-diaminodecane.

Example 21. p-Xylylenediamine CsA Dimer (4). The p-xylene diamine CsA Dimer (4) was prepared by replacing the tris(2-aminoethyl)amino with 0.45 eq. of p-xylylene diamine.

Following procedures described in the literature other derivatives of cyclophilin are prepared by linking at a site other than the 1(MeBmt 1) site.

Position 8 D-isomer analogues are produced by feeding the producing

organism with the D-amino analogue to obtain incorporation specifically at that site. See Patchett, *et al.*, *J. Antibiotics* (1992) 45, 943 (β -MeSO)D-Ala⁸-CsA); Traber, *et al.*, *ibid.* (1989) 42, 591). The position 3 analogues are prepared by poly-lithiation/alkylation of CsA, specifically at the α -carbon of Sac3. See
5 Wenger, *Transplant Proceeding* (1986) 18, 213, supp. 5 (for cyclophilin binding and activity profiles, particularly D-MePhe³-CsA); Seebach, U.S. Patent No. 4,703,033, issued October 27, 1987 (for preparation of derivatives).

Instead of cyclosporin A, following the above-described procedures, other naturally-occurring variants of CsA may be multimerized for use in the
10 subject invention.

Example 22. (A) Structure-Based Design and Synthesis of FK1012-"Bump" Compounds and FKBP12s with Compensatory Mutations

15 Substituents at C9 and C10 of FK506, which can be and have been accessed by synthesis, clash with a distinct set of FKBP12 sidechain residues. Thus, one class of mutant receptors for such ligands should contain distinct modifications, one creating a compensatory hole for the C10 substituent and one for the C9 substituent. Carbon 10 was selectively modified to have either an N-
20 acetyl or N-formyl group projecting from the carbon (vs. a hydroxyl group in FK506). The binding properties of these derivatives clearly reveal that these C10 bumps effectively abrogate binding to the native FKBP12. Figure 23 depicts schemes for the synthesis of FK506-type moieties containing additional C9 bumps. By assembling such ligands with linker moieties of this invention one can
25 construct HED and HOD (and antagonist) reagents for chimeric proteins containing corresponding binding domains bearing compensatory mutations. An illustrative HED reagent is depicted in Figure 23 that contains modifications at C9 and C10'.

This invention thus encompasses a class of FK-506-type compounds
30 comprising an FK-506-type moiety which contains, at one or both of C9 and C10, a functional group comprising -OR, -R, -(CO)OR, -NH(CO)H or -NH(CO)R, where R is substituted or unsubstituted, alkyl or arylalkyl which may be straightchain, branched or cyclic, including substituted or unsubstituted peroxides, and carbonates. "FK506-type moieties" include FK506, FK520 and
35 synthetic or naturally occurring variants, analogs and derivatives thereof (including rapamycin) which retain at least the (substituted or unsubstituted) C2 through C15 portion of the ring structure of FK-506 and are capable of

binding with a natural or modified FKBP, preferably with a K_d value below about 10^{-6} .

This invention further encompasses homo- and hetero-dimers and higher order oligomers containing one or more of such FK-506-type compounds covalently linked to a linker moiety of this invention. Monomers of these FK-506-type compounds are also of interest, whether or not covalently attached to a linker moiety or otherwise modified without abolishing their binding affinity for the corresponding FKBP. Such monomeric compounds may be used as oligomerization antagonist reagents, i.e., as antagonists for oligomerizing reagents based on a like FK-506-type compound. Preferably the compounds and oligomers comprising them in accordance with this invention bind to natural, or preferably mutant, FKBP's with an affinity at least 0.1% and preferably at least about 1% and even more preferably at least about 10% as great as the affinity of FK506 for FKBP12. See e.g. Holt et al, *infra*.

Receptor domains for these and other ligands of this invention may be obtained by structure-based, site-directed or random mutagenesis methods. We contemplate a family of FKBP12 moieties which contain Val, Ala, Gly, Met or other small amino acids in place of one or more of Tyr26, Phe36, Asp37, Tyr82 and Phe99 as receptor domains for FK506-type and FK-520-type ligands containing modifications at C9 and/or C10.

Site-directed mutagenesis may be conducted using the megaprimer mutagenesis protocol (see e.g., Sakar and Sommer, *BioTechniques* 8 4 (1990): 404-407). cDNA sequencing is performed with the Sequenase kit. Expression of mutant FKBP12s may be carried out in the plasmid pHN1⁺ in the *E. coli* strain XA90 since many FKBP12 mutants have been expressed in this system efficiently. Mutant proteins may be conveniently purified by fractionation over DE52 anion exchange resin followed by size exclusion on Sepharose as described elsewhere. See e.g. Aldape et al, *J Biol Chem* 267 23 (1992): 16029-32 and Park et al, *J Biol Chem* 267 5 (1992): 3316-3324. Binding constants may be readily determined by one of two methods. If the mutant FKBP's maintain sufficient rotamase activity, the standard rotamase assay may be utilized. See e.g., Galat et al, *Biochemistry* 31 (1992): 2427-2434. Otherwise, the mutant FKBP12s may be subjected to a binding assay using LH20 resin and radiolabeled T2-dihydroFK506 and T2-dihydroCsA that we have used previously with FKBP's and cyclophilins. Bierer et al, *Proc. Natl. Acad. Sci. U.S.A.* 87 4 (1993): 555-69.

(B) Selection of Compensatory Mutations in FKBP12 for Bump-FK506s Using the Yeast Two-Hybrid System

One approach to obtaining variants of receptor proteins or domains, including of FKBP12, is the powerful yeast "two-hybrid" or "interaction trap" system. The two-hybrid system has been used to detect proteins that interact with each other. A "bait" fusion protein consisting of a target protein fused to a transcriptional activation domain is co-expressed with a cDNA library of potential "hooks" fused to a DNA-binding domain. A protein-protein (bait-hook) interaction is detected by the appearance of a reporter gene product whose synthesis requires the joining of the DNA-binding and activation domains. The yeast two-hybrid system mentioned here was originally developed by Elledge and co-workers. Durfee et al, *Genes & Development* 7 4 (1993): 555-69 and Harper et al, *Cell* 75 4 (1993): 805-816.

Since the two-hybrid system per se cannot provide insights into receptor-ligand interactions involving small molecule, organic ligands, we have developed a new, FK1012-inducible transcriptional activation system (discussed below). Using that system one may extend the two hybrid system so that small molecules (e.g., FK506s or FK1012s or FK506-type molecules of this invention) can be investigated. One first generates a cDNA library of mutant FKBP12s (the hooks) with mutations that are regionally localized to sites that surround C9 and C10 of FK506. For the bait, two different strategies may be pursued. The first uses the ability of FK506 to bind to FKBP12 and create a composite surface that binds to calcineurin. The sequence-specific transcriptional activator is thus comprised of: DNA-binding domain-mutant FKBP12---bump-FK506---calcineurin A-activation domain (where --- refers to a noncovalent binding interaction). The second strategy uses the ability of FK1012s to bind two FKBP12s simultaneously. A HED version of an FK1012 may be used to screen for the following ensemble: DNA-binding domain-mutant FKBP12---bump-FK506---normal FK506---wildtype FKBP12-activation domain.

1. *Calcineurin-Gal4 activation domain fusion as a bait:* A derivative of pSE1107 that contains the Gal4 activation domain and calcineurin A subunit fusion construct has been constructed. Its ability to act as a bait in the proposed manner has been verified by studies using the two-hybrid system to map out calcineurin's FKBP-FK506 binding site.

2. *hFKBP12-Gal4 activation domain fusion as a bait:* hFKBP12 cDNA may be excised as an EcoRI-HindIII fragment that covers the entire open reading frame, blunt-ended and ligated to the blunt-ended Xho I site of pSE1107 to generate the full-length hFKBP-Gal4 activation domain protein fusion.

5

3. *Mutant hFKBP12 cDNA libraries* hFKBP12 may be digested with EcoRI and HindIII, blunted and cloned into pAS1 (Durfee et al, *supra*) that has been cut with NcoI and blunted. This plasmid is further digested with NdeI to eliminate the NdeI fragment between the NdeI site in the polylinker sequence of pAS1 and the 5' end of hFKBP12 and religated. This generated the hFKBP12-Gal4 DNA
10 binding domain protein fusion. hFKBP was reamplified with primers #11206 and #11210, Primer Table:

15

Primer Table: Primers used in the construction of a regionally localized hFKBP12 cDNA library for use in screening for compensatory mutations.

20 Mutant hFKBP12 cDNA fragments were then prepared using the primers listed below that contain randomized mutant sequences of hFKBP at defined positions by the polymerase chain reaction, and were inserted into the Gal4 DNA binding domain-hFKBP(NdeI/BamHI) construct.

25 4. *Yeast strain* *S. cerevisiae* Y153 carries two selectable marker genes (*his3*/ β -galactosidase) that are integrated into the genome and are driven by Gal4 promoters. (Durfee, *supra*.)

Using Calcineurin-Gal4 Activation Domain as Bait The FKBP12-FK506 complex binds with high affinity to calcineurin, a type 2B protein phosphatase. Since we use C9- or C10-bumped ligands to serve as a bridge in the two-hybrid system, only those FKBP12s from the cDNA library that contain a compensatory mutation generate a transcriptional activator. For convenience, one may prepare at least three distinct libraries (using primers 11207-11209, Primer Table) that will each contain 8,000 mutant FKBP12s. Randomized sites were chosen by inspecting the FKBP12-FK506 structure, which suggested clusters of residues whose mutation might allow binding of the offending C9 or C10 substituents on bumped FK506s. The libraries are then individually screened using both C9- and C10-bumped FK506s. The interaction between a bumped-FK506 and a compensatory hFKBP12 mutant can be detected by the ability of host yeast to grow on *his* drop-out medium and by the expression of β -galactosidase gene. Since this selection is dependent on the presence of the bumped-FK506, false positives can be eliminated by subtractive screening with replica plates that are supplemented with or without the bumped-FK506 ligands.

Using hFKBP12-Gal4 Activation Domain as Bait Using the calcineurin A-Gal4 activation domain to screen hFKBP12 mutant cDNA libraries is a simple way to identify compensatory mutations on FKBP12. However, mutations that allow bumped-FK506s to bind hFKBP12 may disrupt the interaction between the mutant FKBP12—bumped-FK506 complex and calcineurin. If the initial screening with calcineurin as a bait fails, the wildtype hFKBP12-Gal4 activation domain will instead be used. An FK1012 HED reagent consisting of: native-FK506—bumped-FK506 (Figure 16) may be synthesized and used as a hook. The FK506 moiety of the FK1012 can bind the FKBP12-Gal4 activation domain. An interaction between the bumped-FK506 moiety of the FK1012 and a compensatory mutant of FKBP12 will allow host yeast to grow on *his* drop-out medium and to express β -galactosidase. In this way, the selection is based solely on the ability of hFKBP12 mutant to interact with the bumped-FK506. The same subtractive screening strategy can be used to eliminate false positives.

In addition to the *in vitro* binding assays discussed earlier, an *in vivo* assay may be used to determine the binding affinity of the bumped-FK506s to the compensatory hFKBP12 mutants. In the yeast two-hybrid system, β -gal

activity is determined by the degree of interaction between the "bait" and the "prey". Thus, the affinity between the bumped-FK506 and the compensatory FKBP12 mutants can be estimated by the corresponding β -galactosidase activities produced by host yeasts at different HED (native-FK506-bumped-FK506) concentrations.

Using the same strategy, additional randomized mutant FKBP12 cDNA libraries may be created in other bump-contact residues with low-affinity compensatory FKBP12 mutants as templates and may be screened similarly.

10 Phage Display Screening for High-Affinity Compensatory FKBP Mutations

Some high-affinity hFKBP12 mutants for bump-FK506 may contain several combined point mutations at discrete regions of the protein. The size of the library that contains appropriate combined mutations can be too large for the yeast two-hybrid system's capacity (e.g., $>10^8$ mutations). The use of bacteriophage as a vehicle for exposing whole functional proteins should greatly enhance the capability for screening a large numbers of mutations. See e.g. Bass et al, *Proteins: Structure, Function & Genetics* 8 4 (1990): 309-14; McCafferty et al, *Nature* 348 6301 (1990): 552-4; and Hoogenboom, *Nucl Acids Res* 19 15 (1991): 4133-7. If the desired high-affinity compensatory mutants is not be identified with the yeast two-hybrid system, a large number of combined mutations can be created on hFKBP12 with a phage vector as a carrier. The mutant hFKBP12 fusion phages can be screened with bumped-FK506-Sepharose as an affinity matrix, which can be synthesized in analogy to our original FK506-based affinity matrices. Fretz et al, *J Am Chem Soc* 113 4 (1991): 1409-1411. Repeated rounds of binding and phage amplification should lead to the identification of high-affinity compensatory mutants.

(C) Synthesis of "Bumped (CsA)2s": Modification of MeVal(11)CsA

As detailed above, we have demonstrated the feasibility of using cyclophilin as a dimerization domain and (CsA)₂ as a HOD reagent in the context of the cell death signaling pathway. However, to further optimize the cellular activity of the (CsA)₂ reagent one may rely upon similar strategies as described with FK1012s. Thus, modified (bumped) CsA-based oligomerizing reagents should be preferred in applications where it is particularly desirable for the reagent to be able to differentiate its target, the artificial protein constructs, from endogenous cyclophilins.

One class of modified CsA derivatives of this invention are CsA analogs in which (a) NMeVal11 is replaced with NMePhe (which may be substituted or unsubstituted) or NMeThr (which may be substituted or substituted on the threonine betahydroxyl group) or (b) the *pro-S* methyl group of NMeVal11 is replaced with a bulky group of at least 2 carbon atoms, preferably three or more, which may be straight, branched and/or contain a cyclic moiety, and may be alkyl (ethyl, or preferably propyl, butyl, including t-butyl, and so forth), aryl, or arylalkyl. These compounds include those CsA analogs which contain NMeLeu, NMelle, NMePhe or specifically the unnatural NMe[betaMePhe], in place of MeVal11. The "(b)" CsA compounds are of formula 2 where R represents a functional group as discussed above.

1 (R = Me) : CsA

2 (R ≠ Me) : Modified [MeVal¹¹]CsA

3

This invention further encompasses homo- and hetero-dimers and higher order oligomers containing one or more such CsA analogs. Preferably the compounds and oligomers comprising them in accordance with this invention bind to natural, or preferably mutant, cyclophilin proteins with an affinity at

least 0.1% and preferably at least about 1% and even more preferably at least about 10% as great as the affinity of CsA for cyclophilin.

A two step strategy may be used to prepare the modified [MeVal¹¹]CsA derivatives starting from CsA. In the first step the residue
 5 MeVal11 is removed from the macrocycle. In the second step a selected amino acid is introduced at the (former) MeVal11 site and the linear peptide is cyclized. The advantage of this strategy is the ready access to several modified [MeVal¹¹]CsA derivatives in comparison with a total synthesis. The synthetic scheme is as follows:

10

15

20

To differentiate the amide bonds, an *N,O* shift has been achieved between the amino and the hydroxyl groups from MeBmt1 to give IsoCsA (Ruegger et al, *Helv Chim Acta* 59 4 (1976): 1075-92) (see scheme above). The reaction was carried out in THF in the presence of methanesulfonic acid. (Oliyai et al, *Pharm Res* 9 5 (1992): 617-22). The free amine was protected with an acetyl group with pyridine and acetic anhydride in a one-pot procedure. The
 25 overall yield of the *N*-acetyl protected IsoCsA is 90%. The ester MeBmt1-

MeVal11 bond is then reduced selectively in the presence of the N-methyl amide bonds, e.g. using DIBAL-H. The resulting diol is then transformed to the corresponding di-ester with another acid-induced *N,O* shift. This will prepare both the *N*-acetyl group and MeVal11 residues for removal through hydrolysis of the newly formed esters with aqueous base.

After protection of the free amino group the new amino acid residue is introduced e.g. with the PyBrop coupling agent. Deprotection and cyclization of the linear peptide with BOP in presence of DMAP (Alberg and Schreiber, Science 262 5131 (1993): 248-250) completes the synthesis of 2. The binding of bumped-CsAs to cyclophilins can be evaluated by the same methods described for FK506s and FK1012s. Once cyclophilins are identified with compensatory mutations, bumped (CsA)₂ HED and HOD reagents may be synthesized according to the methods discussed previously. Of particular interest are bumped CsA compounds which can form dimers which themselves can bind to a cyclophilin protein with 1:2 stoichiometry. Homo dimers and higher order homo-oligomers, heterodimers and hetero-higher order oligomers containing at least one such CsA or modified CsA moiety may be designed and evaluated by the methods developed for FK1012A and (CsA)₂, and optimize the linker element in analogy to the FK1012 studies.

Mutant cyclophilins that bind our position 11 CsA variants (2) by accomodating the extra bulk on the ligand may be now be prepared. Cyclophilins with these compensatory mutations may be identified through the structure-based site-directed and random mutagenesis/screening protocols described in the FK1012 studies.

It is evident from the above results, that the subject method and compositions provide for great versatility in the production of cells for a wide variety of purposes. By employing the subject constructs, one can use cells for therapeutic purposes, where the cells may remain inactive until needed, and then be activated by administration of a safe drug. Because cells can have a wide variety of lifetimes in a host, there is the opportunity to treat both chronic and acute indications so as to provide short- or long-term protection. In addition, one can provide for cells which will be directed to a particular site, such as an anatomic site or a functional site, where therapeutic effect may be provided.

Cells can be provided which will result in secretion of a wide variety of proteins, which may serve to correct a deficit or inhibit an undesired result, such

as activation of cytolytic cells, to inactivate a destructive agent, to kill a restricted cell population, or the like. By having the cells present in the host over a defined period of time, the cells may be readily activated by taking the drug at a dose which can result in a rapid response of the cells in the host. Cells can be
5 provided where the expressed chimeric receptor is intracellular, avoiding any immune response due to a foreign protein on the cell surface. Furthermore, the intracellular chimeric receptor protein provides for efficient signal transduction upon ligand binding, apparently more efficiently than the receptor binding at an extracellular receptor domain.

10 By using relatively simple molecules which bind to chimeric membrane bound receptors, resulting in the expression of products of interest or inhibiting the expression of products, one can provide for cellular therapeutic treatment. The compounds which may be administered are safe, can be administered in a variety of ways, and can ensure a very specific response, so as not to upset
15 homeostasis.

All publications and patent applications cited in this specification are herein incorporated by reference as if each individual publication or patent application were specifically and individually indicated to be incorporated by reference.

20 Although the foregoing invention has been described in some detail by way of illustration and example for purposes of clarity of understanding, it will be readily apparent to those of ordinary skill in the art in light of the teachings of this invention that certain changes and modifications may be made thereto without departing from the spirit or scope of the appended claims.

We claim:

1. A DNA construct encoding a chimeric protein comprising (a) at least one receptor domain, capable of binding to a selected ligand, fused to (b) a heterologous additional protein domain capable of initiating a biological process upon exposure to the ligand, said ligand being capable of binding to two or more chimeric protein molecules.
2. A DNA construct of claim 1 wherein the chimeric protein further comprises an intracellular targeting domain capable of directing the chimeric protein to a desired cellular compartment.
3. A DNA construct of claim 2 wherein the intracellular targeting domain comprises a secretory leader sequence, a membrane spanning domain, a membrane binding domain or a sequence directing the protein to associate with vesicles or with the nucleus.
4. A DNA construct of claim 1 wherein the chimeric protein has a K_D value for binding to the selected ligand of less than or equal to about 10^{-6} M.
5. A DNA construct of claim 1 wherein the selected ligand is less than about 5 kDa in molecular weight.
6. A DNA construct of claim 1 wherein the heterologous additional protein domain comprises:
 - (a) a protein domain capable, upon exposure to the ligand, of initiating a detectable intracellular signal;
 - (b) a DNA-binding protein; or
 - (c) a transcriptional activation domain.
7. A DNA construct of claim 6 wherein the intracellular signal is capable of activating transcription of a gene under the transcriptional control of transcriptional control element responsive to said oligomerization.
8. A DNA construct of claim 7 wherein the additional protein domain is the zeta subunit of CD3.

9. A DNA construct of any of claims 1-8 wherein the chimeric protein is capable of binding to an FK506-type ligand, a cyclosporin A-type ligand, tetracycline or a steroid ligand.
10. A DNA construct encoding a target gene under the transcriptional control of an transcription control element responsive to the oligomerization of a chimeric protein of any of claims 1-9.
11. A DNA construct of claim 10 in which the target gene is not naturally under the transcriptional control of the responsive transcriptional control element.
12. A DNA construct containing (a) a transcriptional control element responsive to the oligomerization of a chimeric protein of claims 1-9 and (b) flanking DNA sequence from a target gene permitting the homologous recombination of the transcriptional control element into a host cell in association with the target gene.
13. A DNA construct of claims 10 - 12 wherein the target gene encodes a surface membrane protein, a secreted protein, a cytoplasmic protein or a ribozyme or an antisense sequence.
14. A DNA vector containing a DNA construct of any of claims 1-13 and a selectable marker permitting transfection of the DNA construct into host cells and selection of transfectants containing the construct.
15. A DNA vector of claim 14 wherein the vector is a viral vector.
16. A viral vector of claim 15 which is an adeno-, adeno associated- or retroviral vector.
17. A chimeric protein encoded by a DNA construct of any of claims 1-9.
18. A cell containing and capable of expressing at least one DNA construct of any of claims 1-13.

19. A cell of claim 18 which is a mammalian cell.
20. A cell of claim 18 which contains
- (a) a first DNA construct encoding a chimeric protein comprising (i) at least one receptor domain capable of binding to a selected ligand and (ii) another protein domain, heterologous with respect to the receptor domain, but capable, upon oligomerization with one or more other like domains, of triggering the activation of transcription of a target gene under the transcriptional control of a transcriptional control element responsive to said oligomerization; and
 - (b) a target gene under the expression control of a transcriptional control element responsive to said oligomerization;

and which following exposure to the selected ligand expresses the target gene.

21. A cell of claim 18 which contains a first set of DNA constructs encoding
- (a) a first chimeric protein containing a DNA-binding domain and at least one receptor domain capable of binding to a first selected ligand moiety ; and
 - (b) a second chimeric protein containing a transcriptional activating domain and at least one receptor domain capable of binding to a second selected ligand (which may be the same or different from the first selected ligand moiety); and

and a second DNA construct encoding a target gene under the transcriptional control of a heterologous transcriptional control sequence which binds with the DNA-binding domain and is responsive to the transcriptional activating domain;

which cell expresses the target gene following exposure to a substance containing the selected ligand moiety(ies).

22. A DNA composition comprising
- (a) a first DNA construct encoding a chimeric protein comprising (i) at least one receptor domain, capable of binding to a selected ligand, fused to (ii) a heterologous additional protein domain, capable of initiating a biological process upon exposure to the ligand; and
 - (b) a second DNA construct encoding a target gene under the transcriptional control of an transcription control element responsive to the oligomerization of a chimeric protein.

23. A DNA composition comprising
- (a) a DNA construct encoding a first chimeric protein comprising (i) at least one first receptor domain, capable of binding to a selected first ligand moiety, fused to (ii) a heterologous additional protein domain capable of initiating a biological process upon exposure to the ligand in the presence of a second chimeric protein; and,
 - (b) a DNA construct encoding the second chimeric protein comprising (i) at least one receptor domain, capable of binding to a selected second ligand moiety, fused to (ii) a heterologous additional protein domain capable of initiating a biological process upon exposure to the ligand in the presence of the first chimeric protein;

wherein the first and second receptor moieties may be the same or different and the first and second selected ligand moieties may be the same or different; and

- (c) a target DNA construct encoding a target gene under the transcriptional control of a transcriptional control element responsive to the oligomerization of a chimeric protein.

24. A ligand capable of binding to two or more chimeric protein molecules of claims 1-9 to form an oligomer thereof, said ligand having the formula:

wherein n is an integer from 2 to about 5, rbm(1)-rbm(n) are receptor binding moieties which may be the same or different and which are capable of binding to the chimeric protein(s), said rbm moieties being covalently attached to a linker moiety which is a bi- or multi-functional molecule capable of being covalently linked ("—") to two or more rbm moieties.

25. A ligand of claim 24 which has a molecular weight less than about 5 kDa.
26. A ligand of claim 24 wherein the rbm moieties are the same or different and comprise an FK506-type moiety, a cyclosporin-type moiety, a steroid or tetracycline.
27. A ligand of claim 24 which binds to a naturally occurring receptor with a Kd value greater than about 10^{-5} .
28. A ligand of claim 24 wherein at least one rbm comprises a molecule of FK506, FK520, rapamycin or a derivative thereof modified at C9, C10 or both.
28. A ligand of claim 24 wherein the linker moiety comprises a C2-C20 alkylene, C4-C18 azalkylene, C6-C24 N-alkylene azalkylene, C6-C18 arylene, C8-C24 ardiakylene or C8-C36 bis-carboxamido alkylene moiety.
29. The use of a ligand of claim 24 to prepare a pharmaceutical composition for activating the transcription of a target gene.
30. A method for activating the transcription of a target gene in cells which comprises
- (a) providing cells containing and capable of expressing (i) at least one DNA construct of claim 7 and (ii) a target gene under the expression control of a transcription control element responsive to the oligomerization of said DNA construct; and,

- (b) exposing the cells to a ligand capable of binding to the chimeric protein encoded by the DNA construct in an amount effective to result in expression of the target gene.
31. A method of claim 30 wherein the cells are grown in a culture medium and the exposing is effected by adding the ligand to the culture medium.
32. A method of claim 30 wherein the cells are present within a host organism and the exposing is effected by administering the ligand to the host organism.
33. A method of claim 32 wherein the host organism is a mammal and the ligand is administered by oral, bucal, sublingual, transdermal, subcutaneous, intramuscular, intravenous, intra-joint or inhalation administration in an appropriate vehicle therefor.
34. A method for providing a mammal responsive to a ligand of claim 24 which comprises introducing a cell of claim 18 into a host mammal.
35. A method for providing a mammal responsive to a ligand of claim 14 which comprises introducing at least one vector of claim 14 into a host mammal under conditions permitting transfection of one or more cells of the host mammal.
36. A kit which comprises at least one DNA construct of any of claims 1-9.
37. A kit of claim 36 which further comprises a ligand to which one or more of the chimeric proteins encoded by the DNA construct(s) bind.
38. A kit of claim 37 which further comprises a monomeric ligand reagent as an antagonist for ligand-chimeric protein binding.
39. A kit of claim 36 which further comprises at least one DNA construct of claims 10 - 13.
40. A kit containing a first DNA construct encoding a chimeric protein containing at least one receptor domain (capable of binding to a selected

ligand), fused to a transcriptional activator domain; a second DNA construct encoding a second chimeric protein containing at least one one receptor domain (capable of binding to a selected ligand), fused to a DNA binding domain; and a third DNA construct encoding a target gene under the control of a transcriptional control element containing a DNA sequence to which the DNA binding domain binds and which is transcriptionally activated by exposure to the ligand in the presence of the first and second chimeric proteins.

40. A kit of any of claims 36 - 38 in which each DNA construct is linked to a selection marker, which may be the same or different for each different DNA construct, permitting the selection of cells which contain said DNA construct(s).

41. A kit of any of claims 36-38 in which one or more of the DNA constructs contains a cloning site in place of an action domain or target gene.

42. A kit of claim 39 which further comprises positive control cells stably transformed with the DNA construct(s) which are provided in the kit.

43. A host organism containing a cell of claim 18.

44. A host organism of claim 43 which is a plant or animal organism.

45. An animal of claim 44 which is a worm, insect or mammal.

46. A mammal of claim 45 which is a mouse or other rodent or a human.

Regulated Transcription Of Targeted Genes And Other Biological Events

Abstract Of The Disclosure

5 Dimerization and oligomerization of proteins are general biological control mechanisms that contribute to the activation of cell membrane receptors, transcription factors, vesicle fusion proteins, and other classes of intra- and extracellular proteins. We have developed a general procedure for the regulated (inducible) dimerization or oligomerization of intracellular proteins. In principle, 10 any two target proteins can be induced to associate by treating the cells or organisms that harbor them with cell permeable, synthetic ligands. To illustrate the practice of this invention, we have induced: (1) the intracellular aggregation of the cytoplasmic tail of the ζ chain of the T cell receptor (TCR)-CD3 complex thereby leading to signaling and transcription of a reporter gene, (2) the 15 homodimerization of the cytoplasmic tail of the Fas receptor thereby leading to cell-specific apoptosis (programmed cell death) and (3) the heterodimerization of a DNA-binding domain (Gal4) and a transcription-activation domain (VP16) thereby leading to direct transcription of a reporter gene.

 Regulated intracellular protein association with our cell permeable, 20 synthetic ligands offers new capabilities in biological research and medicine, in particular, in gene therapy. Using gene transfer techniques to introduce our artificial receptors, one can turn on or off the signaling pathways that lead to the overexpression of therapeutic proteins by administering orally active "dimerizers" or "de-dimerizers", respectively. Since cells from different 25 recipients can be configured to have the pathway overexpress different therapeutic proteins for use in a variety of disorders, the dimerizers have the potential to serve as "universal drugs". They can also be viewed as cell permeable, organic replacements for therapeutic antisense agents or for proteins that would otherwise require intravenous injection or intracellular expression 30 (e.g., the LDL receptor or the CFTR protein).
